According to the scales of the method “Sense-Bearing and Life Orientations” (Muzdybaiev, 1998) servicemen of group MWE had one of the lowest indicators (lower than in the 5th group). Their indicators of the methods “Locus of Control” (Ksenofontova, 1999) and “Will-Regulated Personality” (Hutkin and Mikhalchenko, 2000) moved indicators closer to group WE (it had the lowest quantity of statistically important differences). Unlike group WE they had significantly better indicators of the scale “Negation of Activity”, they had more readiness to act to overcome the differences, as well they had higher level of confidence in possibility to run their own lives, they did not tend to shift their responsibility on others due to results of cooperation, and they had significantly higher indicators of “Self-Reliance”. That indicated their high level of self-reliance and low level of dependency in professional and interpersonal relations in comparison with participants from group WE

DISCUSSION

The research demonstrated that servicemen with the lowest effectiveness of combat operations had the highest indicators through all the motives unlike those with higheffectiveness. However, this case wasnot the realization of the law of Yerkes and Dodson (1908). It was likely that the received data demonstrated the phenomenon of forming the tangentiality of awakening and of free motivation which were described by the Eastern European psychology by Lieontievym (1975) and Byhotskym (1983), by phenomenon of self-efficiency proposed by the American psychology Bandura (1994) who considered that the success of activity was determined not only by the attractiveness of result, but also by the trust in their personal powers.

Thus, to estimate the motivation appropriately there was a need to include servicemen of distinguished groups into motivational types which consisted of content, hierarchy, intensity of motives and their possibility to be implemented.

In that way highly effective servicemen choosing profession considered its content, expressed eagerness to realize themselves in their profession, comply with it, develop in profession, and acquire the professional skills. They rejected dependency and unlawful benefit as motives of profession selection. For relevant motivation of HEit was typical to have eagerness to execute posed tasks and to meet expectations. It was important for them to do socially beneficial work which was understood by them as the only source of income. Important peculiarity of their motivation was the preservation of high professional ambitions – they struggled for professional development, tough tasks, and high estimation of their achievements. Motives which described the conditions andregime of work, social cooperation were non-essential. Servicemen with high effectiveness were characterized as those who had high level of life understanding, significant life prospects, and considered themselves to be strong personality with sufficient will of selection. They were assured that people could control their lives, could make decisions by themselves, and could implement them. Existing content of motivation was supported by high level of internality and developed qualities of will. Thus, servicemen of group HE took ultimate responsibility for their actions having analyzed them, they did not avoid any work, could plan, and put efforts by themselves to achieve the results they struggled for and whichthey were not ashamed of. Their responsibility spreadon the results of professional activity and interpersonal communication as well as on the health. Their obtained level of internality was, first of all, their own experience of successes and fails. Strong-willed quality of servicemen from the group with high efficiency were well-developed and, first of all, met the requirements of their professional activity including tough and unsafe character of their profession as well as cruel normative settlement.

Servicemen with weak effectiveness, as it was already mentioned, had significantly high indicators of all the scales which described the motives of activity and its selection and slight differentiation of those motives. This data gave possibility to talk about insufficiently formed randomness of activity which was presented by inability to cope with desires, low level of self-reliance and reluctance to overcome difficulties. Servicemen from group WE depended on their desires as well as on their surrounding. They wanted to have simple, comfortable work which was usually occupied by them thanks to the patronage of people from their close surrounding.

Presented features of servicemen from groups HE and WE on the indicators of combat activity correlated with the situations concerning the connection between Public Service Motivation (PSM) with work effectiveness and its mediated self-efficiency (Breaugh, Ritz, and Alfes, 2018).

According to it servicemen from group HE was depicted as the type which was guided by motivation of public service, and servicemen from group WE as dependent motivational type.

Servicemen from group MLE1 had highly expressed motivation of a performer which was based on conscious trust in their commanders and marked qualities of will.

Those servicemen were orientated namely on military profession acquiring (high points for the motives of professional selection) and on making efforts to master it. They were responsible and determined concerning the execution of their tasks. They agreed to execute tough tasks, routine actions, and were undemanding concerning the working conditions. It was quite important for those servicemen to have high salary, recognition of their achievements, conformity of social expectations, and support of friendly relations.

Having compared motives of groups HE and MLE1 it was possible to conclude that they had plenty of common aspects concerning their motives of public service and prosocial motivation (Schott, Neumann, Baertschi, and Ritz, 2019). According to that data servicemen from group MLE1 were included into prosocial motivational type. Besides that, the description of this type was supported by the data received by Gillet, Becker, Lafrenière, Huart, and Foiquereau (2017). They determined that servicemen with the highest indicators of autonomous motivationfelt high organizational support, commander’s support, positive experience, and high level of communicationbecause they were engaged into professional activity due to their pleasure, personal choice, and personal will, demonstrated the highest level of well-being.

Servicemen of group MLE2 were the only participants among all the distinguished types who chose their profession being led by their own mercenary interests, possibility to work with things they liked and were interested in, those activities were full of romantic, but not of objective content of the profession. They used social relations to be “on good standing” with their commanders or to gain satisfaction from communication. Those servicemen did not want to realize their strong-willed qualities. Such servicemen required constant control from the side of commanders because they could be addicted to the “romantic” features of their profession neglecting its core sense. The description of this group of servicemen was close to the definition of motivational type proposed by Stéphanie Vincent Lyk-Jensen and Ane Glad (2018) – “Personal Benefit”. Thus, servicemen from group MLE2 were included into romantic (struggle for adventures) motivational type. Servicemen of this type searched for adventures, challenges; however, they were unstable concerning the hardships of service, the actions of combat factors of stress and, usually, these servicemen resigned after the first contract expired.

Servicemen of group MHE choosing the military profession considered its content and were ready to make everything possible to acquire it; however, this motivation lost its urgency. Acquiring the profession they concentrated on financial benefits, personal ambitions, and comfortable conditions of work; they were weakly motivated to put efforts to acquire new profession. It was useful for them to be orientated on the nearest future. Most of professional actions were executed automatically without any strong-willed efforts. They did not get along with their surrounding and showed low level of tolerance. This type was determined as a stagnated one. Nevertheless, even if this type had quite high indicators of effectiveness the general prospects for this type were pessimistic. In accordance with Voet, Steijn, and Kuipers (2017), who distinguished positive relations between the eagerness of changes and prosociality, group MHE was likely to decrease its altruistic behaviour.

Servicemen of group MWE chose the military profession because of its content as well as of his/her own desire to change the life and social status for better. In urgent situation it was important for them to have understandable and well-paid activity which would give them the possibility to improve their social status and conditions of lifeinternally. These servicemen did not feel themselves ready for intellectual and creative work. They did not cooperate with their surrounding and that fact detained the process of professional socialization. Despite the desire to help other people, work, endeavour, and change, they did not achieve high effectiveness in professional activity as a serviceman due to their concentration on defeating the difficulties of life. This type having analogy with Maslow (1943) was marked as a deficient type of motivation. The determination of deficient type of motivation of servicemen who joined the army to change their lives for better, to get new prospects, all those factors were not something new in military psychology. That was the way the American researchers pointed out that military service was often joined by Afro-Americans and people from Latin America, not so often it was joined by people who positively studied at school, planned to enter the college and by parents who graduated from the Higher Educational Establishments (Bachman, Segal, Freedman-Doan, and O’Malley, 2000).

CONCLUSION

Conducted research gave the possibility to determine 6 motivational types related to the effectiveness of servicemen’s operational activity. These motivational types were located between the poles which were introduced by two dimensions: self-efficacy (autonomous and controlled motivation) and motivation of helping others (motivations of public service – selfishness). Those motivational types of servicemen were motivated by public service, stagnant, prosocial, romantic, deficient and dependent. Distinguished types included the content, hierarchy, intensity of motives and their possibility to implement them.

Developmentof the motivation diagnostics of the applicants to the military service on the basis of their determinationto one of the distinguished motivational types would help to decrease the quantity of mistakes during the prediction of effectiveness of operational activity.

Copper and its role in the human body – the importance of establishing copper concentrations in the body

Oana R. Avram[1], Genica Caragea[2], Camelia A. Varzaru[2]

Abstract: *Copper is essential to all living beings, as a food mineral, being an essential component of the cytochromoxidase enzymes complex. It is also an essential component of several systems involved in the production of hemoglobin, of sugar metabolism, of catecholamines' synthesis and in the formation of cross-links between collagen, elastin and keratin fibers within the hair. The dysregulation of copper through impaired absorption or excretion, either genetically based or in acute or chronic poisoning, results in deficiency or toxicity. For this reason, the measurement of copper levels in various biological samples: urine, blood, or hair, provides the physician with information regarding contamination, poisoning, or a metabolic disease. Due to low concentrations in most heavy metals' and metalloids' cases, finding traces in biological samples is a difficult problem. Classical methods (staining, flame photometry, reagent kits, electrochemical methods) can only be used for a limited number of elements, such as sodium, potassium, calcium, magnesium, copper, iron and zinc. The analysis of biological samples is the most important use of graphite furnace atomization. The advantages of using this technique are its great sensitivity and the very low quantity of sample necessary for performing the measurement.*

In modern medicine, determining microelements is very important in diagnosing diseases and/or in treating them. The GF-AAS method is quick, reproductible and has very good sensitivity.

Keywords: *copper, toxicity, metabolism disorders, Wilson disease, determination methods, spectrophotometry, GF-AAS*

INTRODUCTION

A great number of chemical elements in nature are present in the body, either as standalone components, or bound one to another, forming organic and inorganic substances that facilitate or create various disorders in the human body. A part of them (Co, Cr, Cu, Fe, Mg, Mn, Mo, Ni, Se, Sr and V) are essential to life.

Other elements (As, Ba, Be, Cd, Li, Hg, Pb, Sb, Sn) are considered toxic, and their concentrations in any given biological product is preferred to be close to nil. When such concentration is different from zero, the value is considered normal if it is lower than the limit established by toxicology authorities around the world.

Copper is a chemical element that has been used for thousands of years in alloyes. Its compounds are frequently found as copper (II) salts, which usually yield the blue or green colours of minerals, such as azurite or turquoiuse, and have been largely used as pigments. Copper sulfate forms are bright blue crystals containing five molecules of water [$CuSO_4 \cdot 5H_2O$]. It is commonly known as the "Blue Vitriol" or "Blue Stone" [1] and it is used mainly for agricultural purposes as a pesticide, and in the leather industry [2, 3].

Biological Roles of Copper

Copper is essential to all living beings, as a food mineral, as

[2] "Cantacuzino" National Military-Medicine Research Institute

Corresponding author: Genica Caragea
ginacaragea@yahoo.com

it is an essential component of the cytochromoxidase enzymes' complex. It is found in the liver in vertebrates. In high concentrations, copper compounds are toxic for evolved organisms, and are used as bacteriostatics and fungicides.

Copper alloys have intrinsical natural properties that kill a large number of microorganisms, such as E. coli O157: H7, methicillin-resistant Staphylococcus aureus (MRSA), Clostridium difficile, influenza virus A, adenovirus, fungi [4, 5]. Some copper 355 alloys have been shown to kill more than 99.9% of germs within two hours, when properly cleaned [4]. The United States Environment Protection Agency (EPA) has authorized these copper alloys as „antimicrobial materials with public health benefits" [4]. Recent biotechnological researches use copper ions coupled with indocyanine and proteins in targeted cancer treatments [6].

Proteins which contain copper have several biological roles in electron and oxygen transport, processes in which interconversion of Cu (I) and Cu (II) easily takes place [7]. The biological role of copper began the moment oxygen appeared in our planet's atmosphere [8].

In the cytochrome-c oxidase, which is necessary for aerobic respiration, copper and iron work together to reduce oxigen. Copper is found in superoxide-dismutase, which catalyzes the breakdown of superoxides, through conversion to oxygen peroxide and hydrogen:

$$2\ HO_2 \rightarrow H_2O_2 + O_2$$

Copper is an essential component of several systems involved in the production of hemoglobin, in sugar metabolism, in catecholamine biosynthesis, and in forming cross-links between collagen, elastin and keratin fibers within hair.

Copper deficits leads to growth and behavioural disorders, especially in children [9]. Copper deficiency is an etiology of anemia, neutropenia, and bone marrow dysplasia that may be under-recognized, being a possible cause of medical errors in clinical practice [10, 11]. The mechanism of anemia in copper deficiency may be related to the role of copper-dependent enzymes, such as ceruloplasmin and cytochrome-c oxidase, in iron metabolism and transportation [12]. Bone marrow findings of marked vacuolization of both erythroid and myeloid precursors have been consistently reported, and ring sideroblasts are also occasionally reported [13].

Kinetics of Copper

Copper intake is mainly achieved through diet : it is easily absorbed, but its absorbtion is limited by homeostatic mechanisms, after requirements have been met. The human body contains aproximately 1.4-2.1 mg/kg of copper [14]. Copper is absorbed in the gut, then transported to the liver bound to albumin [15]. After being processed in the liver, it is then distributed to other tissues. Copper transportation involves a protein called ceruloplasmin, which also transports copper excreted in milk [16]. The body is able to excrete excessive levels of copper, if necessary, through the bile. The excreted excess is not reabsorbed by the intestine [17, 18]. In catalytic oxidation processes, metalloproteins containing copper are also necessary, as they intervene in oxygen metabolism. Also, copper also acts in oxidative phosphorylation reactions. Copper intake from food can also prevent certain diseases or deficiencies, such as allergies, hair loss, AIDS, leukemie, osteoporosis and gastric ulcer. Together with iron, copper helps in red blood cells' synthesis.

Copper metabolism disorders

The dysregulation of copper through impaired absorption or excretion results in deficiency or toxicity, as illustrated by two rare genetically based diseases.

Wilson's disease was first described in 1912 by Kinnear Wilson as "progressive lenticular degeneration". Wilson's disease can manifest itself at birth, but signs and symptoms only appear when copper accumulates in the brain, liver, or another organ. The signs and symptoms vary with the body part that is affected by the disease and can include fatigue, loss of appetite or abdominal pain, jaundice, brown-golden Kayser-Fleischer rings, muscular stiffness, lack of motor coordination, speech impairment and others.

Menkes' disease, when the body cannot stock copper, leading to its deficiency; it is also known and the uncombable hair syndrome (hair lacks in color, is sparse, wiry and rough, with occasional nodosities) or Menkes' kynky hair disease. It is a rare hereditary X-linked transmitted disease, described by Menkes in 1962 as a severe degenerative disease of the nervous system. Biologically, serum copper and ceruloplasmin levels markedly decrease. Some of the clinical manifestations pertaining to this disease are facial dysmorphia, signs of neuropsychic involvement, hypothermia, skeletal manifestations similar to those in scurvy, and the irregular lumen of blood vessels.

Clinical signs in copper intoxication

In acute intoxication, serum copper reaches very high values, ceruloplasmin and hepatic copper are within normal limits, and urine copper is increased.

In chronic intoxication, serum, urinary copper and ceruloplasmin are increased, and hepatic copper reaches very high values. The acute toxicity of copper in humans is likely due to the generation of reactive oxygen species, which deteriorate DNA [10]. A minimal dietary value of at least 3 ppm was reported for healthy growth in rabbits [20]. However, high concentrations of copper (100 ppm, 200 ppm, sau 500 ppm) in their diets can favorably alter their growth rates [21].

Copper toxicity is determined by the balance between copper intake and excretion. Voluntary copper salts intake, copper intake from food and beverages, inhaling dust which contains copper or aerosols which contain copper salts, through manual spraying of insecticides or fungicides, represent the main risks of exposing the human body to copper contamination.

The main actions of copper on the human body are gastrointestinal irritation, liver and renal disorders, intravascular hemolysis and shock. Acute intoxication following ingestion of copper salts targets the GI tract, cardiovascular and circulatory systems, hematopoietic system, liver, kidneys and nervous system.

The respiratory effects following inhalation are: acute exposure to copper vapors targets the respiratory pathways and chronic exposure to copper salts, seen in those who spray plants, targets the lungs.

The local, irritating effects, through cutaneous or eye contact with copper salts, are seen at skin and eye level.

Other diseases in which abnormalities in copper metabolism appear to be involved include Indian childhood cirrhosis (ICC), endemic Tyrolean copper toxicosis (ETIC), and idiopathic copper toxicosis (ICT), also known as non-Indian childhood cirrhosis. ICT is a genetic disease recognized in the early twentieth century primarily in the Tyrolean region of Austria and in the Pune region of India [22].

DETERMINING COPPER CONCENTRATIONS IN BIOLOGICAL PRODUCTS

Due to low concentrations in most heavy metals' and metalloids' cases, finding traces in biological samples is a difficult problem. Classical methods (staining, flame photometry, reagent kits, electrochemical methods) can only be used for a limited number of elements, such as sodium, potassium, calcium, magnesium, copper, iron and zinc.

Modern methods replace these types of tests. Elements can be determined through atomic absorbtion spectrometry AAS with flame atomization FAAS or graphite furnace atomization GTAAS, inductively coupled plasma and atomic emission spectrometry ICP-AES or inductively coupled plasma and mass spectrometry ICP-MS. ICP-MS is the most sensitive method for determining metals and metalloids, but it also has the highest cost. For determining metals and metalloids in biological samples, the GTAAS method is recommended. For Na+, K+, Cl-, Ca2+ it is much more cost effective to use machines which only measure blood or urine concentrations of these ions, through electrochemical methods.

The analytical method used to determine the concentration of studied elements, from the analyzed matrices, is the atomic absorbtion spectrometry coupled with graphite furnace atomization GF-AAS (Graphite Furnace Atomiser – Atomic Absorbtion Spectrometry). Atomic absorbtion spectrometry is an analytical method used to quantitatively measure metals or metalloids in a sample, based on the quantity of light that is absorbed or emitted by atoms, from a line that is characteristic for the specter of light the atom emits in an excited state.

The first method that was used to bring atoms to an excited state was heat emanated by a flame. The temperature of this flame is approximately 1200 – 13000C. Due to the low temperatures that can be achieved with this method, the sensitivity of this type of atomization is not useful in determining the majority of elements in biological samples.

Graphite furnace atomization has become very useful in analytical chemistry, as a technique which is very good for determining trace elements in a wide variety of sample types. The principle of this method, of achieving a controlled temperature, using electrical current, makes it perfectly reproductible, compared to flame atomization. The greatest advantage, however, consists in the high atomization temperatures, which can never be attained with a flame, which makes analyzing trace elements in biological samples possible.

The number of replicates (repeatedly performing the same determination) is very important for obtaining quality results. Thus, the working program allow real-time quality control of obtained results, by verifying the standard deviation of replicates. If the value of the square mean deviation (standard deviation) of values measured in the same sample exceeds the pre-established value, the system performs the determination once more. The usually admitted standard deviation is 4-5%. The increase of replicates' number increases the duration of a given determination, wears down the graphite furnace, but improves the accuracy of the results. Due to the marked stability of the machine, it is possible to use the minimum number of two replicates.

The absorbance signal has its own noise due to the variations in emitted light, due to its transmission through the optical chain, due to variations caused by the photomultiplier and the electronic system which amplifies the electric signal. This type of noise can be removed by mathematical methods. The methods which may be applied are either in 3, 5, or 9 points. The calibration method is extremely important for the accuracy of the results. For this reason, choosing an optimal calibration method is one of the most important decisions in establishing the method. For standard calibration, the software automatically chooses the liniar calibration. The calibration curbe may or may not pass through point zero. When measured levels are very low, this curve must pass through point zero. Quality control is mandatory to establish the accuracy of the obtained results. Quality control also involves checking: the standard deviation of replicates; the correlation coefficient of the calibration curve; the detection limit of the method and the apparatus.

Table 1: Concentrations of some essential trace elements in blood and urine (mg/l).

Element	**Serum** (μg/L)	**Blood** (μg/L)	**Urine** (μg/L)
Chromium	0.5	0.5	10
Cobalt	0.2	2.0	100
Copper	1100	1200	60
Iron	1200	-	180
Magnesium	0.5	5	300
Molibdenum	1.0	100	100
Nickel	5.0	5.0	85
Selenium	100	100	30
Strontium	50	-	150
Vanadium	0.5	4.0	16

In urine spot samples, there was a great variation in copper content, which is why collecting 24h urine and sampling from the total volume is recommended. The conventional level taken as diagnostic of Wilson's Disease is >100 mg/24 hours in symptomatic patients [23].

A method to determine the concentration of an element in the matrix involves establishing the working conditions of the spectrometer, of the graphite furnace atomizer, of the sample dispenser and the conditions for the automatic quality control of the test.

The calibration curves of the elements, absorbance as a function of concentration, are calculated with the following equation:

$$A/C = a + b * A + cA^2$$

where: A – is the sample absorbance, C – is the sample concentration, A, b, c, d – are coefficients of the calibration curve.

The determination of copper in biological samples is usually carried out for diagnosing Menkes or Wilson disease or for monitoring the distribution and the amount of copper removed during dialysis procedures of patients with chronic renal disease [24, 25].

In order to develop a method for determining direct GF-AAS copper in biological samples (blood and urine) the establishment of operating parameters for atomic absorption spectrometer system – AAS 880 Spectra Varian and for graphite tube atomizer – GTA 100 is of major importance.

The utilized wavelength must be a part of the absorbtion specter of copper and depends on the type of sample. It may be 327.4 nm or as alternative wavelengths, 324.8 nm or 217.9 nm or 218.2 nm. The correct choice is made with the purpose of eliminating the non-atomic absorbtion which may appear during sample analysis. The width of the used diaphragm is of 0.2 or 0.5 nm and its size depends on the type of analyzed sample.

Method for determining the level of copper in whole blood samples

The samples were analyzed with a system formed from the following components:

- Atomic absorbtion spectrometer AAS-880.
- Graphite tube atomizor GTA-100.
- Programmable sample dispenser – PSD.
- Water cooler – Neslab CFT 22.
- Nitrogen generator - Dominick Hunter.
- Gas cylinder (Argon) 99.9999% purity

Optimized working parameters for determining copper levels in whole blood

In order to determine the Cu concentration in the blood samples taken from patients (2 ml of venous blood, taken on anticoagulants), the following method was used:

- Pipetting method – automixing;
- Quantity of injected sample – 10 µl;
- Measurement method – peak height;
- Concentration calibration;
- Smoothing – 9 points;
- Number of replicates - 2 for standard and for sample;
- Cathode tube current – 4 mĂ;

- Wavelength – 327.4 nm;
- Slit width - 0.5 nm;
- Background correction – deuterium lamp;
- Drying – 1200C;
- Calcination - 8000C;
- Atomization - 23000C;
- Cleaning - 25000C;
- Three-point calibration curve – 0, 50 and 100 µg/l;
- Recalibration rate – 15;
- Method detection limit <1.0 µg/l.
- Apparatus detection limit <0.04 µg/l.

Automatic quality control – dispersion <10 %; correlation coefficient of calibration curve >0.998.

The optimization of the temperature program must provide optimal conditions for the measurement of Cu signals by GF-AAS, free of interferences from the background which is a very common problem in the analysis of biological samples (26). The application of the optimized temperature program made possible to eliminate the whole matrix of the sample before the atomization step, as confirmed by the low background signals observed in the measurement of Cu. No chemical modifiers were added. However, biological samples must undergo a deproteinization process, which is meant to eliminate non-atomic absorbance.

Table 2: Established and optimized steps for GTA 100

Step	Temp C	Time s	Flow L/min	Gas Type	Read	Signal Storage
1	40	5	3	N_2	No	No
2	80	10	3	N_2	No	No
3	105	5	3	Ar	No	No
4	105	10	3	Ar	No	No
5	800	20	3	Ar	No	No
6	800	5	3	Ar	No	No
7	800	2	0	Ar	No	Yes
8	2650	0.9	0	Ar	Yes	Yes
9	2650	2	0	Ar	Yes	Yes
10	2650	3	3	Ar	No	Yes
11	40	30	3	N_2	No	No
12	40	5	0	N_2	No	No

Copper stock standard solution containing 1000 mg/L copper was diluted with a premixed solution of distilled water and analytical grade concentrated nitric acid to provide working standards of various concentrations in 0,1% (w/v) HNO3. The calibration blank solution used throughout was a 0.1% w/v HNO3 solution. For copper, the working standards were 100 and 50 µg/L.

Table 3: Performance parameters of linear regression analysis

Conc. ug/L	Abs	Abs. Average	STDEV	RSD %
0	0.0193	0.0183	0.0014	7.55
0	0.0167			
0	0.0188			
50	0.3996	0.4001	0.0009	0.23
50	0.4012			
50	0.3996			
100	0.7214	0.7178	0.0034	0.47
100	0.7147			
100	0.7174			

The whole blood sample (200 µL) was treated with 800 µL solution 5% antifoam B (Sigma) and with 1000 µL of 1.6 M HNO3 solution. The mixture was maintained for 20 minutes and centrifuged with 5000 rpm for 5 min. The supernatant was analyzed by GF-AAS. The results are obtained in µg/dL. A linear relationship was found between the absorbance at 327.4 nm and the concentration of cooper in the range of 0.0 to 100 µg/L. The representative linear equation was y = 0,007x + 0,029 where: y is the absorbance, x is lead concentration (µg/L), calculated by the least squares method. The regression coefficient (r) standard curve was 0.9972, indicating good linearity (r > 0.99).

The performance parameters of linear regression equation are presented in Table 3. The parameters of the GF-AAS analysis method of lead are presented in Table 4. LOD and LOQ were calculated based on the standard deviation and the slope of the regression line.

Table 4: Validation parameters

Standard error	0.0173
R Square	0.9972
Intercept	0.0290
Slope	0.0070
SE of intercept	0.0091
LOD (µg/L)	***4.29***
LOQ (µg/L)	***13.01***

LOD is the lowest concentration of an analyte that can be detected while LOQ is defined as the lowest concentration of an analyte that can be determined at the acceptable level of precision and accuracy and were calculated according to the formula below: LOD = 3,3*(SD of intercept/Slope) and LOQ = 10*(SD of intercept/Slope)

The established method can be easily used to perform copper measurements in the laboratory, both in urine and blood samples taken from patients suspected for copper intoxication. Copper deficiency and toxicity can be either of genetic or non-genetic origin. The study of copper's genetic diseases, which are the focus of intense international research activity, has shed insight into how human bodies use copper, and why it is important as an essential micronutrient.

The evolution of the copper concentration in urine or whole blood provides very useful information for poisoning diagnostic when the history is not clear [27, 28].

CONCLUSIONS

Microelements play an important role in the normal course of life. The variation of their blood levels within the body can lead to metabolic disturbances. For example, copper deficiency is found in Menkes syndrome or ,,uncombable hair disease”, and copper excess leads to Wilson’s disease. The rise in blood levels of copper can also be due to acute intoxication, for example, as a result of spraying plants with copper sulphate.

For these reasons, measuring Cu concentrations in various biological samples, urine, blood, or hair, provides the physician with information regarding contamination, intoxication or the existence of a metabolic disease.

The analysis of biological samples is the most important use of graphite furnace atomization. The advantages of this technique are its high sensitivity and the very low quantity of sample necessary for the measurement.

In modern medicine, determining trace elements is very important in diagnosing various diseases and/or in treating them. The GF-AAS is a quick, reproductible and highly sensitive method.

The Author retains all rights not granted to the Publisher in writing.

The Author will submit all required materials relating to the work to the Publisher before the Publisher will perform any services. Required materials are: the final manuscript in a form acceptable to the Publisher (including all changes and corrections); all image files or image hardcopies; any and all other materials supplied by, or agreed to be supplied by, the Author for inclusion in the work. The Publisher reserves the right to refuse any submitted material for any reason at any time at its sole discretion. If the Publisher refuses to publish the manuscript submitted by the Author, the Publisher will be under no obligation to return any submitted materials. In no event will the Publisher be obligated to publish a work, which in its opinion violates the common law or statutory copyright, or the right of privacy of any person, or contains libelous or obscene material.

The Publisher will design the work's layout in consultation with the Author. The Publisher will, however, retain final discretion over the style and formatting of the work.

The Author represents and warrants to the Publisher: that he/she is the sole owner of the work and of all the rights granted to the Publisher; that he/she has not assigned, pledged, or otherwise encumbered the rights to the work; that he/she has full power to enter into this Agreement; that the work and all rights therein are free of liens, claims, or interests of any kind; that the work is entirely original except for portions thereof for which legally effective written licenses or permissions have been secured; that the work does not violate or infringe upon any personal or proprietary rights including without limitation privacy rights, contract rights, or publicity rights of any other persons or entities; that the work is not libelous or obscene; that the work does not infringe upon any statutory or common law copyright; that any information contained in the work is accurate, and any recipe, formula, or instruction contained in the work is not injurious to the reader or to any other party.

If any claim, action, or proceeding based upon an alleged violation of any of these warranties is made (i) the Publisher will have the right to defend the same through counsel of its own choosing, (ii) no settlement will be effected without the prior written consent of the Author, which consent will not unreasonably be withheld, and (iii) the Author will hold harmless the Publisher, any seller of the work, and any licensee of a subsidiary right to the work, against any damages finally sustained. If such claim, action, or proceeding is successfully defended or settled, the Author will indemnify the Publisher against the entire expense (including reasonable counsel fees) attributable to such defense or settlement. If any such claim, action, or proceeding is instituted, the Publisher will promptly notify the Author, who will fully cooperate in the defense thereof, and the Publisher may withhold payments of reasonable amounts due the Author under this or any other agreement between the parties. These warranties and indemnities will survive the termination of this Agreement.

If the Author incorporates in the work any copyrighted material, he will attempt to procure permission to use copyrighted materials. The Publisher in no way guarantees that it will be able to procure said permission and will not be held liable if permission cannot be obtained. The cost of copyright permissions and their procurement will be solely the responsibility of the Author.

If the copyright of the work is infringed and the parties (the Author and the Publisher) proceed jointly, the expenses and recoveries, if any, will be shared equally, and if they do not proceed jointly, either party will have the right to prosecute such action, and such party will bear the expenses thereof, and any recoveries will belong to such party; and if such party will not hold the record title of the copyright, the other party hereby consents that the action be brought in his/her name.

This Agreement and the rights and licenses granted in the License of Rights paragraph above will extend indefinitely until terminated by either party. Either the Author or the Publisher may terminate this Agreement at any time, with or without cause.

Any notice given under this Agreement is deemed to have been given if deposited in the Romanian mail, certified postage pre-paid, addressed to either party at the locations given above, or any other addresses as hereafter provided by either party.

The laws of the Romania will govern this Agreement. Any dispute or controversy arising under, out of, in connection with, or in relation to this Agreement, and any amendments thereof, will be determined and settled by arbitration in accordance with the rules of the Romanian legislation.

This Agreement may not be modified or amended except by the written agreement of the parties.

This Agreement constitutes the entire agreement between the parties with respect to the matters covered by it, and supersedes any prior understanding or agreements, oral or written, with respect thereto. The parties will not be bound by any understanding, agreement, promise, or representation, whether expressed or implied, which is not specified in this Agreement.

Correlation between FibroScan and AST/ALT ratio and splenic size in NASH patients in a tertiary care center

Varsha Somakumar[1], V.S. Srikanth[2], Cibi Manoharan[1], Vishal Marwaha[1], V.R. Mujeeb[2], M.G.K. Pillai[1]

Abstract: *Background: Non-Alcoholic Steatohepatitis (NASH) is an aggressive form of Non-Alcoholic Fatty Liver disease (NAFLD), with liver inflammation and scarring. Due to a lack of clinical biomarkers and asymptomatic nature, NASH is often under-diagnosed. It is the most common cause of chronic liver disease in the USA. Liver biopsy is the gold standard to diagnose NASH, but it is invasive and life-threatening and histologic evaluation of a liver biopsy sample is imperfect as a reference because of sampling variability due to the irregular distribution of fibrosis. Aim: Validating AST/ALT ratio as a stand-alone scoring system in NASH is scarce and so this study aims to establish a correlation between FibroScan values and AST/ALT ratio. Methodology: All NASH patients, who underwent FibroScan were included. Their demographics, FibroScan, AST, ALT values were recorded in M S Excel and Pearson correlation between FibroScan values and AST/ALT ratios of 150 NASH patients was calculated using SPSS. Results: Out of 150 NASH patients, 72% were males and 57.33% belonged to 40-50 years age group. FibroScan values and AST/ALT ratio showed positive Pearson correlation of 0.245, (p value=0.003). FibroScan values and splenic size also showed a positive Pearson correlation of 0.289 (p value<0.001). Conclusion: Males of 40-50 years age group had higher distribution of NASH, so middle aged males should be screened routinely as they are at a higher risk. FibroScan value with AST/ALT ratio and splenic size showed a positive correlation, thus showing that AST/ALT ratio and splenic size increases with increase in liver stiffness.*

Keywords: *NAFLD, NASH, FibroScan, Elastography, AST/ALT*

INTRODUCTION

Nonalcoholic fatty liver disease (NAFLD) is a broad term used for a range of liver conditions affecting people who drink little to no alcohol, and is the most common cause of chronic liver disease in the United States of America [1], affecting approximately 90% of the obese population and 15-40% of the general population [2]. As the name implies, the main characteristic of NAFLD is excessive fat stored in the hepatic cells of the liver [1]. It consists of a spectrum of conditions: benign steatosis or non-alcoholic fatty liver (NAFL), steatosis accompanied by inflammation and fibrosis or nonalcoholic steatohepatitis (NASH), and finally cirrhosis [3].

The rising prevalence of NAFLD globally may be accounted for by changes in dietary habits and an increase in sedentary lifestyle [4]. Insulin resistance and oxidative stress play an important role in NAFLD development and progression [5]. Due to the lack of clinical biomarkers as well as its asymptomatic nature, NASH is often under-diagnosed and most commonly found incidentally during routine Ultrasound of the abdomen [3]. No highly sensitive and specific tests are available to differentiate NASH from simple steatosis, but diagnostic accuracy can be improved by combining blood biomarkers [6]. It is an aggressive form of fatty liver disease, marked histologically by liver

[2] Command Hospital Air Force, Bengaluru

inflammation and may progress to advanced scarring (cirrhosis) and liver failure, which is similar to the damage caused by heavy alcohol use. The number of people at risk for NAFLD is even greater given the increasing prevalence of obesity, diabetes and metabolic syndrome [1]. Although steatosis can be a significant cofactor in progression of established CLD, or even hepatocellular carcinoma (HCC), only steatohepatitis indicates the presence of progressive liver disease in patients with NAFLD. Benign and malignant liver tumors have been more frequently reported with the increasing prevalence of obesity and diabetes [7]. Early identification and targeted treatment of patients with NASH are needed to improve patient outcomes, directing patients toward intensive lifestyle modification to promote weight loss as well as for referral for bariatric surgery as indicated [8]. In NAFLD, HCC frequently develops in a not-yet cirrhotic liver; ss there are no surveillance programs for these patients, diagnosis often occurs at a tumor stage beyond curative options, further marking the importance of its early diagnosis [9]. According to a recent study done by Edenvik et al. [10], NAFLD and alcoholic liver disease were more commonly associated with deficient surveillance for HCC, and therefore early diagnosis was missed.

Although liver biopsy is considered the gold standard to diagnose NASH, only those patients with a high risk of NASH or advanced fibrosis require this evaluation, since it is an invasive and potentially life threatening procedure. Non-invasive tools for diagnosis and disease staging are required, reserving liver biopsy for those patients where it offers clinically relevant additional information only [11]. The use of non-invasive tests to stage the severity of liver disease (ie. scarring) is now well established in the management of patients with chronic liver disease since the assessment of liver scarring provides prognostic information and establishes treatment priorities [12]. Techniques such as transient elastography, magnetic resonance elastography and acoustic radiation force imaging are becoming more established in detecting fibrosis in a variety of chronic liver conditions in addition to NAFLD, as reviewed by Fitzpatrick E et al. [13]

One such technique, transient elastography (TE), is a simple, safe and efficient way to estimate liver scarring which is done using FibroScan, and is the most popular non-invasive device used to assess liver 'hardness' (or stiffness) via TE. Liver hardness is evaluated by measuring the velocity of a vibration wave (also called a 'shear wave') generated on the skin [12]. The main clinical indication for liver elastography is fibrosis staging of chronic liver disease and detect advanced fibrosis. Histologic evaluation of a liver biopsy sample is an imperfect reference standard because some degree of sampling variability is inevitable due to the irregular distribution of fibrosis in chronic liver disease.

FibroScan can be easily performed at the bedside or in the outpatient clinic with immediate results for the diagnosis of significant fibrosis and cirrhosis in nonalcoholic fatty liver disease chronic hepatitis C, in recurrence of hepatitis C after liver transplantation, in co-infected HIV-HCV patients, in chronic hepatitis B, in chronic cholestatic diseases, in alcoholic disease [14]. FibroScan evaluates liver stiffness, inflammation and portal hypertension and the values have to be interpreted according to clinical, biological and morphological data. FibroScan® results range from 2.5 kPa to 75 kPa. Between 90–95% of healthy people without liver disease will have a liver scarring measurement <7.0 kPa (median is 5.3 kPa) [12].

The usual observed biochemical pattern in hepatic steatosis due to NAFLD is of increased levels of transaminases, with alanine aminotransferase (ALT) levels exceeding those of aspartate aminotransferase (AST). This classical pattern differentiates between hepatic steatosis from NAFLD and alcoholic liver injury, with the latter normally associated with a high AST/ALT ratio [15]. Generally, the AST to ALT ratio increases with the severity of the necroinflammatory and fibrotic changes [16].

Data validating the use of the AST/ALT ratio as a stand-alone scoring system in NASH is scarce. This study aims to establish a correlation between FibroScan values and AST/ALT ratio. Given the high prevalence of NAFLD in the general population, these noninvasive methods could be used in clinical practice to screen patients with NAFLD [17]. Lifestyle modifications to reduce weight are a major factor in the treatment of NAFLD. No pharmacological substances are as yet approved for the indication NASH [18].

MATERIALS AND METHODS

Out of a total of 2000 patients diagnosed with NASH over a period of 3 years (January 2017 to December 2019) in Amrita Institute of Medical Sciences and Research Centre, Kochi, 150 patients who underwent Transient Elastography Scan (FibroScan) is selected. Inclusion criteria consists of abnormal liver function tests, fatty liver infiltration on ultrasonography (US), undergone FibroScan etc. Exclusion Criteria are patients with a history of alcohol intake, hepatitis B and C, history of hepatotoxic drug intake and other liver diseases. Ethics Comittee of Amrita Institute of Medical Sciences has approved the study.

The mean of 10 elastography values is taken as the FibroScan value. Patient details like their demographics, USG findings, AST/ALT ratio, Neutrophil/Lymphocyte ratio, LFT etc were obtained using their hospital numbers from Amrita Health Information System and recorded in MS Excel.

Pearson correlation of FibroScan values with AST/ALT ratio and splenic size and Receiver Operative Characteristic (ROC) is used to find out optimal cut off for AST/ALT and Splenic diameter, as well as their sensitivity, specificity, and predictive values, using SPSS.

RESULTS

The majority of cases were seen among males (Figure 1). 74% (111) of cases were above 40 years (Table 1 and Figure 2).

Table 1: Distribution of age

Age Group (years)	**Frequency**	**Percent Distribution**
11-20	1	0.6
21-30	15	10
31-40	23	15.3
41-50	38	25.3
51-60	48	32
61-70	22	14.6
71-80	3	2
Total	150	100

Figure 1: Distribution of gender

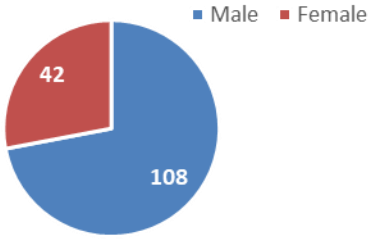

Figure 2: Distribution of age

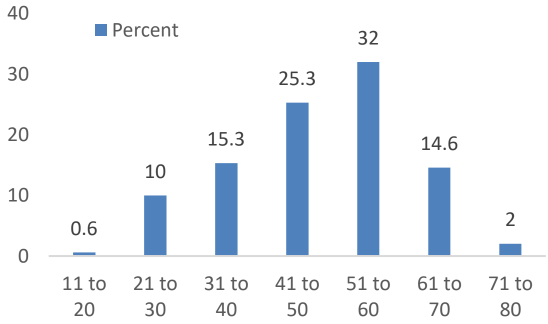

Mean laboratory values are given in Table 2.

Table 2: Demographics and laboratory characteristics

Mean Age	48.4 years
Gender (Males)	108 (72%)
Mean HDL	46.68 mg/dl
Mean LDL	127.34 mg/dl
Mean TG	136.52 mg/dl
Mean AST	72.18 IU/L
Mean ALT	103.72 IU/L
FibroScan	7 kPa
Splenic Size	9.7 cm
Neutrophil	54.12%
Lymphocytes	35.5%
NEU/LYM	2.02

In order check the correlation between FibroScan and AST/ALT (Figure 3), Pearson correlation was used. Positive correlation of 0.245 with a statistically significant P value of 0.003 was obtained. Positive correlation of 0.298 with a statistically significant P value of <0.001 was obtained between FibroScan and Splenic Diameter (Figure 4).

Figure 3: Scatter Plot of FibroScan and AST/ALT

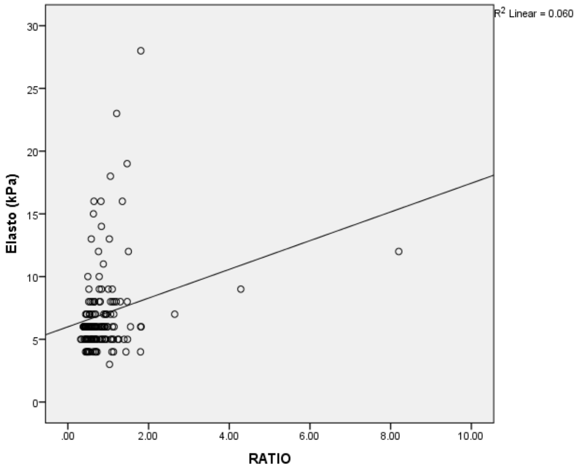

Figure 4: Scatter Plot of FibroScan and splenic size

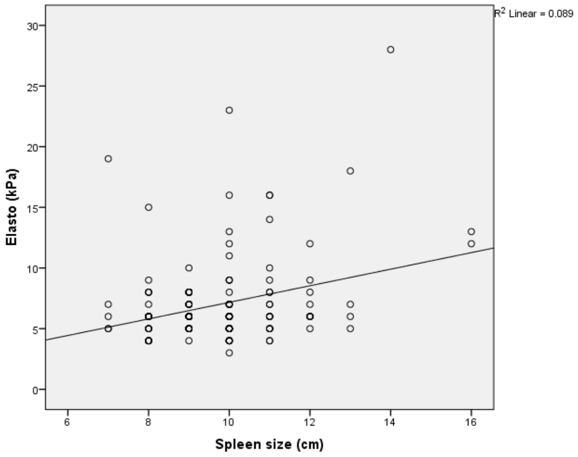

Table 3: Demographics and laboratory characteristics

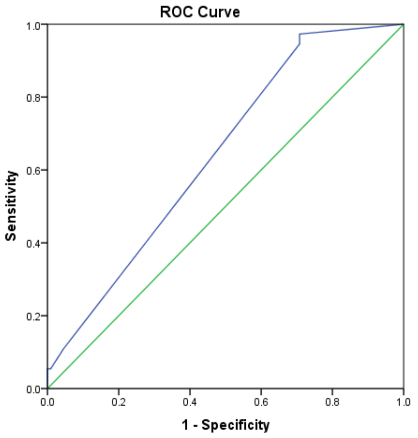
		AST/ALT	Splenic size
Fibroscan	Pearson corrrelation	0.245	0.298
	p-value	0.003	<0.001

ROC curves were used to check the diagnostic accuracy of AST/ALT (Figure 5) which showed an AUROC of 0.641, ASTAST/ALT cut off 0.32 (P value 0.01), with a sensitivity and specificity of 97.3% and 29.2%. ROC for Splenic Diameter (Figure 6) showed an AUROC of 0.60, cut off of 9.5cm (P value 0.06), with a sensitivity and specificity of 62% and 51.3%.

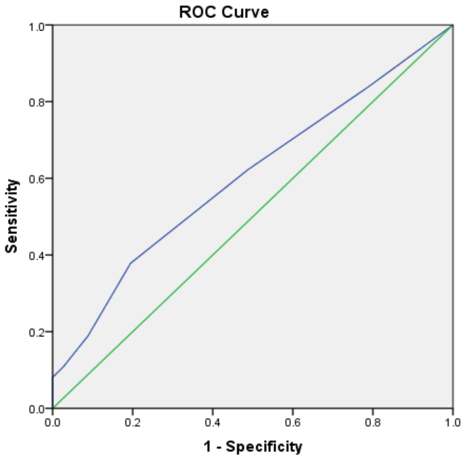
Figure 5: ROC curve for AST/ALT



Diagonal segments are produced by ties.

Area	0.641
AST/ALT	0.32
P value	*0.01*
Sensitivity	97.3%
Specificity	29.2%

Figure 6: ROC curve for Splenic Size



Diagonal segments are produced by ties.

Area	0.603
SS	9.50
P value	*0.061*
Sensitivity	62%
Specificity	51.3%

CONCLUSION

Males of age more than 40 years had higher distribution of NASH, so middle aged males should be screened routinely as they are at a higher risk for developing NASH. FibroScan value with AST/ALT ratio and splenic size showed a statistically significant positive correlation, thus showing that AST/ALT ratio and splenic size increases with increase in liver stiffness. Thus our study shows that AST/ALT ratio can also be used for prompt diagnosis and management of NASH patients.

Costs for a hospital stay: another lesson learned from the COVID-19 pandemic

Aurelian C. Moraru[1], Mariana Floria[1,2], Elena D. Năfureanu[1,2], Diana E. Iov[2], Lăcrămioara I. Şerban[2], Viorel Scripcariu[2], Dragoș M. Popescu[3]

Abstract: *Background and aim: After two years of pandemic, planning and budgeting for use of healthcare resources and services is very important. Inpatient COVID-19 hospitalizations costs, regardless of ICD-10 procedure codes, in a Covid-19 support military hospital were analyzed. Methods: The national protocol for the treatment of Covid-19 infection was applied. The costs for laboratory tests, drugs, protection equipment and radiological investigations (imaging techniques such as computed-tomography or radiography), hospitalization days and food were assessed. Results: In our hospital, from August 2020 through June 2021, 241 patients were hospitalized with COVID-19: mean age 59.92±7.8 years, 46% men, 26% military personnel, 11.57±3 days of hospitalization; two third of patients had moderate and severe forms of COVID-19. The main manifestations were: 69% respiratory (18% with severe pneumonia), 3.3% cardiac (2.9% with pulmonary embolism, diagnosed by computed tomography angiography), 28% digestive and 33% psychiatric (most commonly anxiety). The average estimated costs were about 3000€/patient, without significant differences based on disease severity. Equipment costs were 2 times higher than for drugs and 3 times than for laboratory tests. Conclusions: In a Covid-19 support military hospital that cared for patients with predominantly moderate forms of COVID-19, the costs for equipment were much higher than those for treatment. New criteria for hospitalization of these forms of COVID-19 deserve to be analyzed in order to avoid useless costs.*

Keywords: *COVID-19, pandemic, hospital stay, costs*

INTRODUCTION

SARS-CoV-2 is the most deadly and devastating virus of the last one hundred years, being more contagious than the Ebola virus, HIV, Swine Influenza virus (H1N1, H1N2), Severe Acute Respiratory Syndrome (SARS) or Middle Eastern Respiratory Syndrome (MERS) [1]. COVID-19 is a systemic disease determined by SARS-CoV-2, with a variable degree of severity and progression [2]. The evolution of this infection is mostly as pulmonary disease. Depending on the host's immune response, it may present as a severe form with multiorgan dysfunction, especially if the patient has comorbidities. COVID-19 can have cardiac, renal, digestive or cerebral manifestations. Therefore, it implies significant costs for diagnosis, drugs, hospitalization, protection equipment, etc.

Profiles of COVID -19 patients have been studied in various ways. Besides determining risk factors, influencing treatment protocols, setting priorities for vaccination, or inspiring further research, planning and budgeting for use of healthcare resources and services become very important given the duration of the pandemic. According to health policy researchers, many insurers claim that it is justified to charge patients for COVID-19 hospitalizations now that COVID-19 vaccines are widely available. For example, the hospitalization of a person with private insurance amounts to a total of $42.200 on average, whereas each hospitalization of a person with COVID-19 who has Medicare Advantage coverage averaged about $21.400 [3]. In comparison, the average cost for influenza hospitalization is around $1.000 [4]. Therefore, we emphasize that COVID-19 prevention is better than treating. Nowadays, vaccines targeting SARS-CoV2 are highly effective at preventing the severe forms of the disease, hospitalizations, and deaths

from COVID-19 [5,6]. Despite the wide availability of safe and effective vaccines, vaccination rates have lagged in Romania.

The aim of this study was to analyze the costs of hospital stays in patients with predominantly moderate forms of COVID-19 in a small size military hospital located in Northeast Romania.

METHODS

This study included all patients hospitalized between August 2020 and June 2021 in a military hospital. Inpatient COVID-19 hospitalizations costs, regardless of ICD-10 procedure codes (U07.1), were retrospectively analyzed. The hospital's statistician offered all data about costs. We assessed hospital costs per patient, per severity degree of COVID-19 and per health service type.

Inclusion and exclusion criteria

According to National Center for Surveillance and Control of Infectious Diseases (CNSCBT) the definition of a confirmed COVID-19 case is: a person with laboratory confirmation of SARS-CoV-2 infection (by RT-PCR SARS-CoV-2), regardless of clinical signs and symptoms [7].

All patients with a positive RT-PCR test without complete vaccination were included in the study. Patients in the first 14 days after the first dose of anti-SARS-CoV-2 vaccine were not excluded. Patients with positive COVID-19 rapid tests were tested by RT-PCR. In accordance with the hospitalization protocol instituted after October 15th 2020, asymptomatic patients were no longer hospitalized and were managed in an ambulatory manner.

The local hospital ethics committee approved the study. All patients enrolled in the study gave their written informed consent.

All patients underwent a specific protocol for COVID-19 diagnosis and treatment, adapted by our hospital according to the national protocol.

Diagnosis protocol

Diagnosis protocol included the following exams:

1. RT-PCR for SARS-CoV-2

2. Monitoring of vital functions (temperature, blood pressure, heart rate, respiratory rate, oxygen saturation, diuresis, defecation)

3. Blood tests: complete blood cell count, C-reactive protein, urea, creatinine, blood electrolytes, ALT, AST, GGT, blood glucose, CK-MB, troponin, D-dimers, ferritin, other blood tests depending on comorbidities (presepsin, procalcitonin, TSH, fT4, etc.).

4. Urinary sediment analysis

5. Computed tomography (CT) examination (with or without contrast agent)

6. Electrocardiogram (the presence of sinus rhythm or new bundle branch block, maximum PR and QTc interval)

7. Sputum examination (if necessary)

8. Coproculture, Clostridium difficile toxins (if necessary)

9. Echocardiography (in case of suspected cardiac disease or complication)

10. Arterial gases (in case of impaired respiratory function)

Patient monitoring was done clinically and biologically, with daily biochemistry in patients with moderate or severe forms. Repeated imaging exams and biological tests were performed urgently in case of clinical worsening.

Radiological parameters used for the study were parenchymal involvement scores, CT score and CORADS score (COVID-19 imaging Reporting And Data System). Chest CT findings reported the COVID-19 imaging using CORADS score that divides the CT findings into six categories [8]. It ranges from CORADS category 1 with very low level of suspicion to CORADS category 5 with very high level of suspicion. If none of the five categories can be established due to incomplete or insufficient images, it is considered CORADS category 0. CORADS category 6 indicates proven COVID-19 by positive RT-PCR test results [8].

In addition, a semi-quantitative scoring system for estimating parenchymal abnormality based on the area involved has been used.

Each one of the five lung lobes was individually evaluated and scored based on parenchymal involvement on a scale ranging from 0 to 5, with 0 indicating no involvement, 1 for less than 5% involvement, 2 for 5–25% involvement, 3 for 26–49% involvement, 4 attributed to 50–75% involvement, and 5 indicating more than 75% parenchymal involvement. The total CT score was the sum of the individual lobar scores, which ranged from 0 (no involvement) to 25 (the maximum possible involvement) [9].

Patients were diagnosed with asymptomatic, mild, moderate, severe or critical COVID-19. Most patients with severe forms of the disease who evolved into critical condition with at least one of the following: acute respiratory distress, sepsis, impaired consciousness or multisystem organ failure, were transferred in hospitals with COVID-19 intensive care units.

Treatment protocol

Patients were treated according to the national protocol published by CNSCTB [7]. Asymptomatic cases were hospitalized for medical supervision and were symptomatically treated as mild COVID-19. Moderate forms of the disease, defined as no oxygen requirement, have been treated with antivirals (lopinavir/ritonavir or umifenovir, remdesivir), antibiotics and symptomatically (paracetamol, C vitamin, D vitamin, antitussive drugs). All severe COVID-19 forms required oxygen therapy; they had at least one of the following parameters: respiratory rate ≥ 30/min; $SaO_2 \le 93\%$; PaO_2/FiO_2 <300; pulmonary infiltrates that increased by more than 50% in 24-48 hours. Beside oxygen therapy, they received corticotherapy (dexamethasone), anticoagulation (enoxaparine or fraxiparine in prophylactic or therapeutic doses), antivirals, immunomodulatory drugs (tocilizumab).

The duration of treatment was decided by the physician and was prolonged or shortened according to the patient's clinical evolution, but no case has received medical treatment for less than 10 days (surveying for severe side effects or Covid-19 complications).

Personal protective equipment

All medical personnel used personal protective equipment against SARS-CoV2 and complied with WHO recommendations [10]. Besides medical facemasks, face shields, protective glasses, two types of gloves (examination and surgical) and gowns or aprons, disinfectants and other consumables were used to comply with the rules of aseptic and antiseptic environment.

The study was conducted in accordance to the Declaration of Helsinki and approved by the Ethics Committee of Hospital (protocol code 2021-01).

Statistical analysis

Continuous variables were presented as median and categorical as absolute values and percentages. Normality was verified using the Shapiro-Wilk test. The comparisons of groups were based on a student's two-sample t-tests. P-value ≤ 0.05 was considered statistically significant for all tests. Statistical analysis was performed using SPSS 10 for Windows (SPSS Inc., Chicago, IL, USA).

RESULTS

In the specified time interval, 241 patients were hospitalized with COVID-19.

Patient population

In our study population, 46% were men and mean age was 59.92±7.8 years. Twenty six percent of patients were military personnel and 74% were civilians. The main COVID-19 manifestations were: 69% respiratory (18% with severe pneumonia, 2.9% with pulmonary embolism, diagnosed by angio-computed tomography), 3.3% cardiac, 28% digestive and 33% psychiatric (most commonly anxiety). Only two patients had a procalcitonin level >10 ng/mL (high probability of severe sepsis or septic shock) and 1 patient had moderate risk for septic shock (0.5-2ng/mL). Mean clinical, biological, electrocardiographic and radiological characteristics of patients included in the study were presented in Table 1.

Table 1: Mean clinical, biological, electrocardiographic and radiological characteristics of patients included in the study.

Characteristics	Value (n=241) n (%) or mean ± SD
CLINICAL	
Blood pressure (mm Hg)	130±21/78±19
Heart rate (/min)	82±21
SaO2 (mmHg)	93±17
Smoker (%)	11 (0.045)
BMI (kg/m^2)	32.9±17

Parenchymal involvement scored	3.4
CT score	14/25
CORADS score	5.6

ALT: alanine amino transferase; AST: aspartate amino transferase; BMI: body mass index; CK-MB: creatin kinase MB; CORADS: COVID-19 imaging Reporting And Data System; CRP: C-reactive protein; CT: computed-tomography; O2: oxygen; PR: interval PR; SR: sinus rhythm

According to COVID-19 severity (Table 2), most patients had moderate (104 patients – 43%) and severe (50 patients - 21%) forms. Seven patients with severe forms died because of multiple comorbidities and 30 patients were transferred to hospitals with COVID-19 intensive care units.

Table 2: Distribution of COVID-19 according to disease severity.

COVID-19 severity	Number of patients (%)
Asymptomatic	14 (6%)
Mild	73 (30%)
Moderate	104 (43%)
Severe	50 (21%)
Total	241

Hospitalization costs

Mean hospital stay was 11.57±3 days. In each day of hospitalization, at least 10 healthcare personnel members (4 nurses, 4 carers and 2 physicians) used protective equipment. Eight patients (3.3%) received Remdesivir and 2 patients (0,8%) Tocilizumab. In the first three months of the study, Plaquenil and Kaletra were not available in the hospital's pharmacy, therefore only 23 (9.5%) patients received these drugs. Antibiotics such as ceftriaxone were indicated in 152 (63%) patients. Dexamethasone was used in 190 (78.8%) patients. Prophylactic doses of low molecular weight heparin were administered in 220 (91.3%) patients and therapeutic doses in 7 (2.9%) patients. Asymptomatic patients did not receive anticoagulants.

The mean costs for patient according to disease severity are shown in Table 3, the average estimated costs were about 3000€/patient, without significantly differences depending on disease severity.

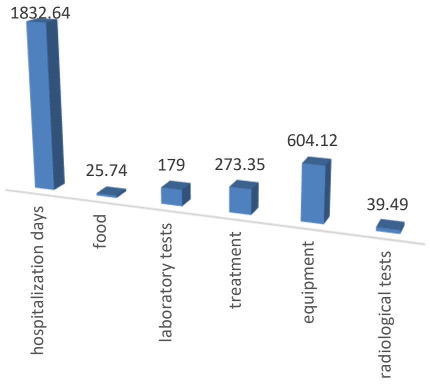
Table 3: The mean costs per patient according to disease severity.

COVID-19 severity	Total costs (€)	Mean costs/pts (€)
Asymptomatic	23410,65	1672,19
Mild	220949,62	3026,71
Moderate	318966,92	3066,99
Severe	148669,86	2973,39
Total	711997,05	10739,28

The costs for hospitalization days, food, laboratory tests, drugs, protection equipment and radiological investigations (imaging techniques such as computed-tomography or radiography) are presented in Figure 1.

Protection equipment costs were 2 times higher than for drugs and 3 times than those for laboratory tests (p<0.0001). However, the sum of hospitalization and protective equipment costs was almost nine times greater than medication costs (2436.76 € versus 604.12 €; p<0.0001).

Figure 1: Mean costs per patient according to each type of health services.



DISCUSSION

Two years after SARS-CoV-2 emerged, the coronavirus continues to affect every aspect of society, one of the major economic effects of the virus being experienced by the health care sector, with COVID-19 changing the economics of health care [11].

The results of our work are a summary of the hospitalization stay costs in patients with COVID-19, in a support hospital from Romania, before the full vaccination scheme was completed.

In August 2020 our hospital was designated as support unit in the battle with COVID. In accordance with this status and due to the fact that we did not have an intensive care unit available for COVID patients, predominantly moderate cases of COVID-19 were hospitalized. A number of patients had an unpredictable evolution to a severe form, some of them presenting exitus from cardiorespiratory arrest while awaiting transfer to an intensive care unit, given the high occupation rate of intensive care units across the country. However, a significant part of our patients (12.4%) was successfully transferred to an intensive care unit dedicated to COVID-19 patients. This explains why there were no differences in costs between moderate and severe forms. In intensive care units the mean costs for invasively ventilated patients in this first part of pandemic was about €10.000 (according to unpublished financial data from these hospitals in Romania).

Medical costs associated with COVID-19 have long been overlooked in previous reports and this is one of the few published studies estimating the costs associated with caring for patients with COVID-19 during hospitalization. In the first part of the SARS-CoV2 pandemic, even patients with asymptomatic forms of the disease were hospitalized. In this study, the cost for hospitalization for this type of patients were two times lower compared to that for symptomatic disease. However, one explanation for this fact could be the rising prices and high costs of personal protective equipment.

Real-time data on the costs of all COVID-19 hospitalizations are far from known. In the US, an average hospitalization cost is around $20.000 [11]. Data published by the Centers for Medicare and Medicaid Services showed that Medicare fee-for-service COVID-19 hospitalizations costs range from $21.752 to $24.033 [11]. Similarly, a FAIR Health analysis of private claims data including employer and private Medicare Advantage plans found that median in-network COVID-19 hospitalization costs ranged from $17.094 for people over the age of 70 to $24.012 for people in their 50s. However, the costs for pneumonia hospitalizations with complications averaged $20.292, but the costs for hospitalizations requiring a ventilator are much higher [12].

According to published data [12], in the US COVID-19 outpatient treatment costs can average $500-$1.000 per patient (average patient age: 39 years). Average treatment costs for patients treated in hospitals compared to patients managed in an outpatient setting for COVID-19 (average patient age: 54 years) was 45 times higher. In addition to this, for the same mean age, average treatment costs for patients treated in intensive care units without the need for ventilation, compared to those whose cases were managed in a medical ward were 2.5 times higher [13]. To our knowledge, costs for hospital stay have not been analyzed by category (personal protective equipment versus drugs, blood test, etc) in literature until now.

In our country vaccination started at the beginning of 2021, therefore the majority of patients were unvaccinated until June 2021. In the US, from June through November 2021, preventable COVID-19 hospitalizations among unvaccinated adults cost over $13 Billion [12]. Therefore, over 690.000 COVID-19 hospitalizations could have been prevented by vaccination between June to November 2021; this is a lesson that must be learned in order to cut down the hospitalization stay costs [12].

In many countries, the impact of COVID-19 on the public health budget was significant. For example, in Spain it comprised 12.3% of total public health expenditure, greater than multiple sclerosis, cancer and diabetes costs [14]. The mean cost per patient was significantly greater than in our study (€10.744). The main costs were staffing costs: for physicians (10.131 to 11.357 €/patient) and for nurses (10.274 to 11.215 €/patient) [14].

A multivariate model was developed to predict the length of hospital stay [15]. The prediction model included five variables: procalcitonin, heart rate, epidemiological history, lymphocyte count and cough [15]. The results showed that the overall length of stay was 11 days (5–15 days) and the median cost for a hospital stay was 7.388.19 RMB (Renminbi) (ranging between 5.085.39–11.145.44) or €1.024.77. Data about hospitalization duration published by Carrera-Hueso et al. [14] and Hong et al. [15] are similar to those in our study, but hospitalization costs were lower, probably due to differences in health service policies.

Another smaller retrospective study (70 patients), which assessed the cost factors and which was conducted at the very beginning of the COVID-19 pandemic, found that the cost for drug acquisition (that accounted for 45.1% of the overall cost) was the major contributor to the medical expenditure. The risk factors for higher costs were pre-existing diseases and severity of COVID-19 [16]. Comparing with this study, at that time, personal protective equipment was not an issue. However, clinical management of COVID-19 patients incurred a great financial burden to many national health systems. In addition, the treatment recommendations changed during this pandemic, each country having an agreed protocol.

Another study that used a Monte Carlo simulation model to estimate resource use and direct medical costs per symptomatic infection at national level found that a single symptomatic COVID-19 case could incur a median direct medical cost of $3.045 during the course of the infection alone [17]. However, a strong limitation of this study is the fact that all models, by definition, are simplifications of real life and cannot account for every possible outcome [18].

In Spain, the European country most economically affected by the pandemic, the gross domestic product cost accounted for 94.7% of the total cost of the COVID-19 and direct health-care costs were 2.14% [19]. This study was designed to analyze the cost-effectiveness of the test-tracking-quarantine strategy, which was the dominant strategy in Spain. Lopez-Valcárcel et al. [19] showed that for each € spent on it, 7 € would be saved in terms of health-care resources. Therefore, this is another important cost-effectiveness strategy in COVID-19 pandemic, similar to those used in an economic evaluation of health-care technologies [20].

Many countries made great efforts to support health-financing flows [21]. A patient with COVID-19 can have a higher probability of hospitalization and mortality than those for other common diseases, therefore hospitalization costs are higher [22-24]. However, before starting this study, on June 18th 2020, the number of confirmed cases across the world had surpassed 8 million. The European region accounts for 31% of cases and 43% of deaths globally [25].

There are some lessons to be learned from the COVID-19 pandemic about improving hospital care and healthcare delivery, both in day-to-day circumstances and future emergencies [26]. One of them is that many countries have learned of the disadvantages of no longer manufacturing certain medical equipment themselves. In addition to that, the reimbursement system of public hospitals seems not to reflect the real COVID-19 costs because the accounting systems of European countries vary widely by the share of reimbursement through DRG (diagnosis-related group based on ICD-10 procedure codes) payment and a reliable accounting system for calculating the actual expenditure per COVID-19 patient (based on actual costs and hospitalization data) is needed [27,28]. Given these issues, it is difficult to compare the costs for hospital stay in patients with COVID-19.

In conclusion, after the COVID-19 pandemic reduced global economic growth by an estimated 3.2% in 2020, with trade declining by 5.3% [29], hospital stay costs might be another lesson, especially given the fact that in Europe 90% of cases recovered in an ambulatory setting [30].

Study limitations

This study included all consecutive patients hospitalized in a single COVID-19 support hospital. In Romania, during the pandemic, hospitals were classified in units treating only COVID-19 cases, COVID-19 support hospitals and non-COVID-19 hospitals. Our hospital was a COVID-19 support unit without endowment of a COVID-19 dedicated intensive care unit. Even if patients were included consecutively, data from this study were analyzed retrospectively. The treatment of COVID-19 patients from this study was, mainly, symptomatic and supportive. These descriptive data provided some practice pattern in the treatment of COVID-19 for the first part of the pandemic.

CONCLUSIONS

In a small-size military hospital designated as COVID-19 support unit that cared for predominantly moderate forms of COVID-19, the costs for equipment were much higher than the treatment costs. Therefore, new criteria for hospitalization of these forms of COVID-19 deserve to be analyzed in order to avoid useless costs. Test-tracking-quarantine or other solutions like vaccination are very important to avoid important future health-care expenditure.

Aknowledgements

We are grateful for all the physicians that cared for the patients included in the study and to Mrs. Ioana Alupei for her administrative and technical support.

Couvelaire-Uterus: literature review and case report

Ionut M. Cobec[1], Andreas Rempen[1]

Abstract: *Uteroplacental apoplexy or Couvelaire uterus is a rare complication in the spectrum of the life-threatening placental abruption.*

We report a 29-year-old pregnant woman who had a placental abruption complicated with the rare condition of Couvelaire uterus, with an delivery per uterus-sparring cesarean section.

The early diagnosis and proper medical management of placental abruption through uterus-sparring cesarean section present the best outcome for mother and child.

Keywords: *uterus Couvelaire, placental abruption, uteroplacental apoplexy*

INTRODUCTION

Utreroplacental apoplexy or Couvelaire uterus is a rare manifestation which complicates aprox. 5% of placenta abruptions and was described for the first time in 1911 by French obstetrician Dr. Alexandre Couvelaire [1, 2]. The placenta abruption complicates ~1% of pregnancies [3] and the maternal mortality can reach up to 5%. The uteroplacental apoplexy is a rare, nonfatal complication of the placenta abruption [4].

A literature search for the last 10 years was conducted on 25.11.2020 using the PubMed database and having the key words 'Couvelaire uterus'. This resulted in 27 articles published in the last 10 years. The Couvelaire uterus is often underreported and underestimated. The etiology is unknown and the diagnosis is done through inspection or histological examination [4].

This mechanism of placenta abruption can be seen as physiological after the fetus delivery and as pathological in the pregnancy with the fetus still in uterus. The acute condition of placenta abruption is the result of a compromise of the vascular structures supporting the placenta, having as outcome a retroplacental hematoma. This process may represent the starting point for Couvelaire uterus. The hemorrhage from pathologic vascular damage within the placenta seeps into the decidua basalis causing a separation of the placenta. Before the second stage of labour is finished, the blood created by bleeding resulting from the early placenta abruption infiltrates into the myometrium finding its way into the peritoneal cavity. Occasionally, such effusions of blood extend in the parametrium. As a result of the described mechanism we notice the macroscopic aspect of Couvelaire uterus which displays lesions characterized by violet to black ecchymoses [5, 6, 7]. The Couvelaire uterus sometimes loses its contractile power but usually responds well to intravenous oxytocin [6, 8]. The uterine ability to contract is preserved, particularly after amniotomy and decompression to allow constriction of spiral arteries [9].

Among the risk factors for placenta abruption are early

cobec_i@yahoo.com

pregnancy bleeding, hypertension or thrombophilia, or abdominal trauma [10]. The diagnose of placenta abruption is made clinical and is completed by the ultrasound scan and CTG. The patients present a painful, tender and rigid uterus, may have uterine contractions, vaginal bleeding is also common. The finding of a retroplacental clot on ultrasound scan is a risk factor for placenta abruption, the ultrasound scan plays an important role correlated to the clinical situation in the diagnose of the placenta abruption [3, 10, 11].

The delay of the diagnose of placenta abruption increase the risk of intrauterine fetal death, hypoxic brain injury, bleeding, coagulopathy with increased maternal and fetal morbidity and mortality [12, 13]. The incidence of coagulopathy in placenta abruption is reported to be 5.8% [3]. In the case of Couvelaire uterus the disseminated intravascular coagulation can be induced through the infusion of thromboplastic material in maternal circulation [14].

Couvelaire uterus was associated in different reports with placenta abruption, placenta previa, amniotic fluid embolism, and preeclampsia [4, 15]. Cesarean section in the patient’s history is a risk factor for uterine rupture, abnormal placental implantation, placental abruption and uterine scar dehiscence in subsequent pregnancies [16]. Some authors consider that the incidence of Couvelaire uterus is increased by the increase in cesarean deliveries [4].

The management of the antenatal and postpartum hemorrhage plays a key role, on one side in the control of the bleeding and blood transfusion, and on the other side aims to reduce fetal and maternal morbidity and mortality [4].

In the past hysterectomy was performed as a routine therapy of Couvelaire uterus. Nowadays, is recommended to opt for the conservative management [4, 8]. The proper management of this pathology reduces the high maternal and fetal risks. The literature reports cases of fetal demise, but also hysterectomy as a result of severe disseminated intravascular coagulopathy [3, 4, 17]. The early decision to perform a hysterectomy taken before the patient's condition is extreme serious is required in order to minimize the morbidity and mortality [18, 19]. On the other hand, before deciding for more aggressive procedures, like hysterectomy, B-Lynch technique should be taken into consideration in cases of postpartum haemorrhage as a result of abruptio placentae followed by development of Couvelaire uterus [19, 20].

In a study on placenta abruption poor perinatal outcome associated with Couvelaire uterus, pregnancy induced hypertension and disseminated intravascular coagulopathy is reported [18].

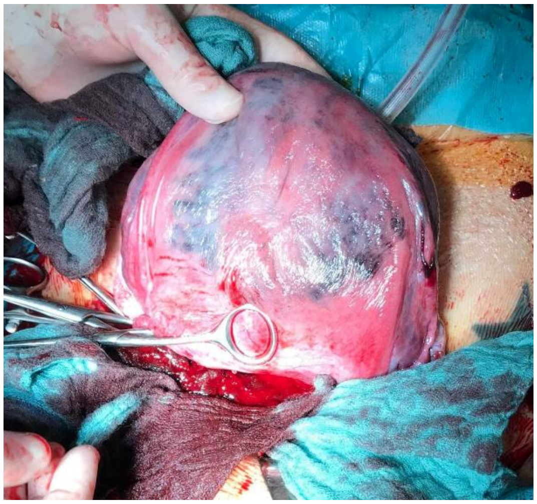
CLINICAL EXAMPLE

A 29-year-old gravida two, para one, in the 37th (36+6) week of an uncomplicated pregnancy, with a history of an uneventful spontaneous delivery, was admitted to the obstetric ward with symptoms of nephrolithiasis and urinary infection for further therapy. The obstetrical check-up was uneventful. The admission symptoms were alleviated, discharge could have been possible but she developed irregular and poorly coordinated uterine contractions. She developed uterine tenderness without relaxation between contractions, with wooden hardness by palpation. Vaginal examination revealed acute hemorrhage from the uterine cavity. The patient was hemodynamically stable. The cervix was 2 cm long and 1 cm dilated. CTG was normal. Cesarean delivery was indicated by suspicion of placental abruption. Intraoperatively massive hemoperitoneum and the diagnose of placenta abruption with Couvelaire uterus was confirmed (Figure 1).

A healthy boy was delivered. Uterus-sparring surgery was performed.

Postoperative recovery was uneventful.

Figure 1: Couvelaire uterus as a result of acute intradecidual hemorrhage produced by the rupture of the uterus–placental spiral arterioles which produces ecchymosis discoloration, secondary to extravasation of blood into the myometrium and serosa, can lead to hemoperitoneum.



DISCUSSION AND CONCLUSION

Placental abruption represents the early separation of the placenta from the uterus wall developing a retroplacental hematoma which is an acute intradecidual hemorrhage produced by the rupture of the uterus–placental spiral arterioles. Couvelaire uterus or uteroplacental apoplexy is the result of blood extravasations in the tissues, occasionally the infiltrations which reach the peritoneal cavity creating hemoperitoneum [1, 2, 5].

In our case, the first intraoperative view after opening the peritoneal cavity was the massive hemoperitoneum and Couvelaire uterus with dark purple and copper color patches with ecchymosis discoloration and hemorrhagic infiltration in the lateral portions of the uterus.

Diagnosis is made through direct inspection or histological examination [2]. The management of this complication of the placenta abruption is conservative through uterus-sparring surgery, hysterectomy is usually not required and should be discouraged [2, 6]. Couvelaire uterus is a rare complication of placental abruption, with an underreported incidence and it is often associated with placenta previa, amniotic fluid embolism, and preeclampsia [4, 15] .

Often Couvelaire uterus is reported with massive placenta abruption requiring blood transfusion [4]. In our reported case blood transfusion was not required. Antenatal fetal and maternal monitoring, but also the delivery on time, plays an important role in the delivery outcome, otherwise due to bleeding it can come to fetal demise [15, 21]. Placental abruption has an increased maternal morbidity risk of haemorrhage, hysterectomy and consumptive coagulopathy [3]. The life-threatening condition of disseminated intravascular coagulation should not be underestimated [3, 18] .

In the reported case the patient was in the hospital under monitoring and the prompt medical decisions reduced the maternal and fetal risks.

The early diagnosis and proper medical management of placental abruption through the uterus-sparring cesarean section provide the best outcome for mother and child.

CoViD-19 disease, Romanian health system response to outbreak and economic impact

Laura Bostangiu (Petcu)[1], Alexandru I. Iordache[2], Nicolae D. Garofil[3], Raluca S. Costache[3]

Abstract: *The pandemic called COVID-19 disease has an exponential course since the first cases were reported showing in 9th of May, 2020, more than 4 million cases of COVID-19. United States and European Council (EC), together with other European Union institutions, were closely monitoring the situation in order to take quick action.*

Objective: The aim of this article is to analyze the response to COVID 19 pandemic outbreak in term of strategy and money flow of Romanian health system in order to identify the strength and weakness and prepare for other similar provocative challenges.

Global and national strategy: United States Government is delivering a comprehensive package of services to support international partners around the world in combatting this disease adding American expertise for global benefit, saving lives by improving international partners abilities to respond to the COVID-19, and reducing secondary impacts. Meanwhile European Union is focused on 6 major coordinates limit the spread of the virus, ensure and provide medical supplies, decrease negative economic impact, support jobs, promoting research and help European citizens to repatriate. Despite all negative elements a proper and relatively quick response of Romanian Public Health System was noticed and the taken measures were harmonized and synchronized with the European coordinates, prioritize initiatives, build an action plan, establish a communication plan, workforce optimization and management strategy.

Conclusion: Global shock needs global response, with little or no government interventions, economic costs will be huge.

Keywords: *COVID-19, SARS-CoV-2, Coronavirus, pandemic financial impact, hospitalization cost*

BACKGROUND

COVID-19, coronavirus disease, is caused by a new type of coronavirus (SARS-CoV-2) and it was first identified in China in December 2019 when an outbreak in the municipality of Wuhan was described as quickly spreading to other regions of China and worldwide [1, 2]. By 7 of January 2020, isolated cases had appeared in some European Union (EU) member states. At the end of February 2020, Italy reported a significant increase of coronavirus disease (COVID-19) cases concentrated in two of the northern regions of the country [3]. By March 2020, all European Union (EU) member states had reported an exponential increase of COVID-19 cases. European Council (EC), together with other EU institutions, is closely monitoring the situation in order to take quick action [3]. This includes approving of relevant European

Union legislation and ongoing coordination with member states to share information, assess needs and ensure a coherent European Union wide response under direct coordination of The World Health Organization (WHO) [3]. On 11 March 2020, the World Health Organization (WHO) declare COVID-19 as global pandemic with an important issue: in this declaration they were talking about geographic spread, and not about the severity of the disease [4].

The pandemic called COVID-19 disease has an exponential course since the first cases were reported showing in 9th of May, 2020, more than 4 million cases. Disease caused by the new coronavirus that was named severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection, COVID-19, have been reported globally with more than 286,000 deaths in 180 countries, including all United States with 1,4 million persons recovered [3, 5].

As epidemiological pattern, all groups of ages are at risk for infection including here severe form of disease, even death. However, seems that the probability of fatal disease is highest in people aged more than 65 years, those with comorbidity and those living in a nursing home or long-term care facility [6, 7, 8]. Of underlying condition, especially when those are not controlled is appropriate to mention as major risk factor for severe or critical COVID-19 disease [3-7]: Hypertension, Obesity, Chronic respiratory disease, Cardiovascular disease, Cancer, Renal disease, Diabetes [9]. As for diagnose WHO recommends as gold standard nasopharynx samples to be used in order to detect SARS-CoV-2. Nasal swabs or oropharyngeal swabs may be acceptable alternatives [9]. Lower respiratory tract samples have a demonstrated higher sensibility than upper tract samples, but WHO recommend not to obtain because of concerns about aerosolization of virus during collection procedures. Regarding treatment, no drug has been proven to be safe and effective for treating COVID-19. There are no Food and Drug Administration (FDA) or EMEA -approved drugs specifically to treat patients with COVID-19. In the medical literature, reports have appeared claiming or promoting successful treatment of patients with COVID-19 using a variety of agents [6, 8, 9]. A single conclusion has emerging: definitive clinical trial data are needed to identify optimal treatments for this disease. General clinical management of patients with COVID-19 includes infection prevention, control measures and supportive care, including supplemental oxygen and mechanical ventilatory when indicated. In is also compulsory to mention that as in the management of any disease, treatment decisions ultimately reside with the patient and their health care provider [6, 7, 9, 10, 11, 12].

Behind the medical challenge generated by COVID-19 pandemic and all concerns, analyst anticipate an economic crisis. That is why worldwide governments are involved in generate measures in order to decrease negative economic impact.

OBJECTIVE

The aim of this article is to analyze the response to COVID 19 pandemic outbreak in term of strategy and money flow of Romanian health system in order to identify the strength and weakness and prepare for other similar provocative challenges.

GLOBAL ANALYSIS AND DISCUSSION

If we have to define the concept of support, probably in the last 50 years the United States (U.S.) will fit perfectly since they have been the largest contributor to global health security [4]. US built the foundation upon which the global health system is based, contributing more than $140 billion in global health assistance only in the last century and nowadays demonstrate leadership in fight to COVID-19 pandemic. From the beginning of the outbreak of COVID-19, the United States government provided more than $500 million in assistance specifically aimed to support anti-pandemic measures [3, 4, 13, 14].

But this is not all, US Government is delivering a comprehensive package of services to support international partners around the world in combatting this disease. The program should add American expertise for global benefit, saving lives by improving international partners abilities to respond to the COVID-19, and reducing secondary impacts [13, 14].

The strategy mentioned is focus to: Save lives by increasing international partners ability to respond to the pandemic; Reduce secondary impacts of the disease; Promote U.S. leadership for global benefit [13].

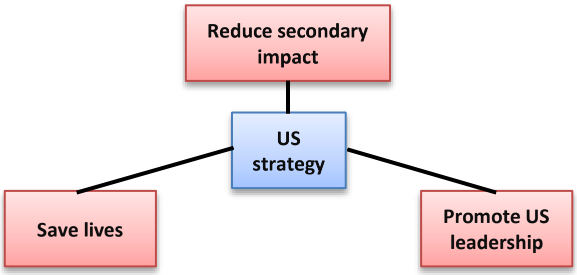

Figure 1: US Strategy for COVID-19 [13, 14]

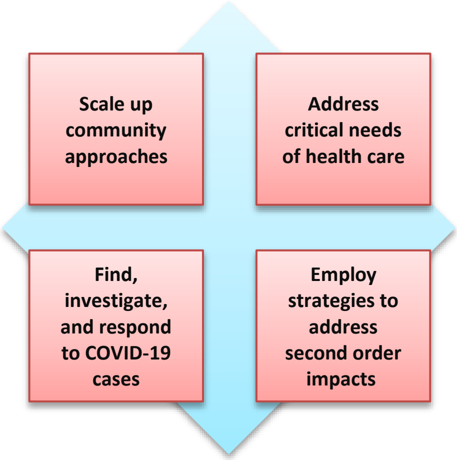
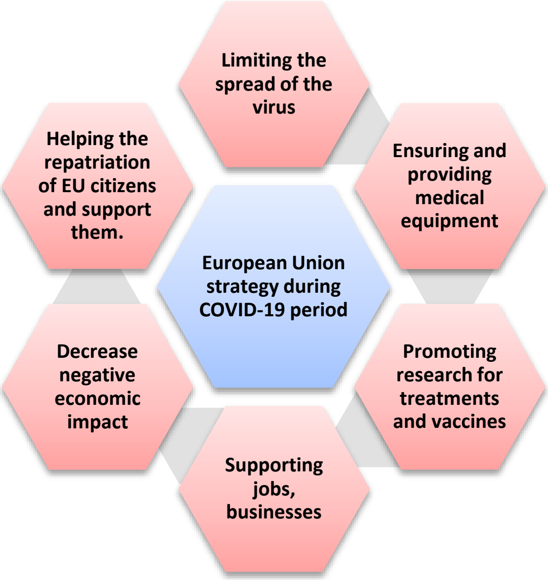
The United States (US) was delivering a SAFE and more secure world from COVID-19 program as is state in the following table [13,14].

The European Union's (EU) response to COVID-19 outbreak focuses on 6 major coordinates as they are mentioned above [15,16].



Scale up community approaches
Address critical needs of health care
Find, investigate, and respond to COVID-19 cases
Employ strategies to address second order impacts

Figure 2: US program SAFE for a safer and more secure world from COVID -19



Limiting the spread of the virus
Helping the repatriation of EU citizens and support them.
Ensuring and providing medical equipment
European Union strategy during COVID-19 period
Decrease negative economic impact
Promoting research for treatments and vaccines
Supporting jobs, businesses

Figure 3: European Union strategy for COVID-19 disease [15, 16]

In order to slow down the transmission of the virus, European Union (EU) leaders agreed on a coordinated temporary restriction of non-essential travel to the EU for 30 days. The travel of European citizens outside the EU acquires negative recommendation. To coordinate the EU response to the COVID-19 outbreak the following measures were taken [15, 16, 17]:

- The Council activated the EU an integrated political crisis response (IPCR) with mandatory weekly roundtables gathering EU institutions, EU agencies experts and representatives of member states
- European Commission and the Council are gathering contact and coordination between relevant national ministries
- The European Centre for Disease Control (ECDC) quantify daily risk assessments and epidemiological updates for the EU population.

By using the union civil protection mechanism, the EU has: coordinated the deployment of medical teams to most affected areas, facilitated the sourcing for additional protective equipment, especially medical masks, activated the Emergency Response Coordination Centre, to coordinate support 24/7, created a new common European reserve of emergency medical equipment including also ventilators and lab supplies. More than €300 million was allocated for research and support initiatives in medical field and a European COVID-19 data portal was launched to ensure the rapid collection and sharing of available research data [15, 16, 18, 19].

The EU and its member states are taking action to minimize the negative impact of outbreak on the economy. On 9 April 2020, the Eurogroup generated, three immediate safety nets, worth €540 billion for: protect and generate new jobs and businesses in member states. The EU is putting forward temporary support to mitigate unemployment risks in an emergency (SURE) to help people keep their job during the crisis. The scheme consists of loans to member states of up to €100 billion to cover the costs related to the creation or extension of national short-time work schemes. European Investment Bank (EIB) Group to create a pan-European guarantee fund providing that way loans up to €200 billion for companies with a focus on small and medium-sized enterprises (SMEs) throughout the EU [15, 17, 18, 19].

European Stability Mechanism set up Pandemic Crisis Support based on an existing credit line, which will include loans available to all euro area member states up to 2% of their internal product estimated at €240 billion. The EU also has increased its budget for 2020, with €3.1 billion as response to the COVID-19 crisis [18, 19]. This additional fund will be used to purchase and distribute medical supplies, including protective gear and ventilators, boost the production of testing kits, build mobile hospitals, transfer patients for treatment in between member states, repatriate EU citizens stranded abroad [19].

The EU has also adopted measures to ensure additional flexibility in the use of structural funds. On behalf of

Coronavirus Response Investment Initiative Plus member states can transfer money between different capital lines in order to meet their needs, resources can be redirected to the most affected regions and the opportunity request up to 100% financing from the EU budget between 1 July 2020 and 30 June 2021 for programs involving measures with impact in the COVID-19 pandemic [15, 16]. The EU and its member states were working to repatriate more than 650.000 EU citizens stranded abroad. EU countries and EU delegations provide consular assistance to help EU citizens return home, providing 75% of the costs of the return flights and add measures in order to help them to cross EU borders [16].

Although Li at all [10] estimate that 86% of all infections were undocumented prior to 23 January 2020, when travel restrictions were beginning per person, the transmission rate of undocumented infections was 55% from all of documented cases. Due to their increasing factor, undocumented patients were the source for 79% of documented cases [12]. They conclude that two favorable condition are rising: existing estimates of case-fatality rates might be over-estimate and a grade of immunity is present in the system [12]. But they underline also that probably when interventions started in Europe and US the virus was already widely spread and simulation regarding on how measures of suppression will flatten the curve in the short period may be over-optimistic [12].

NATIONAL STRATEGY AND HEALTH ECONOMIC IMPACT

Geopolitical context

Romania is one of the countries that has to face the infection of the population with the new coronavirus. The most recent statistics shows that Romania has around 4.7 mil people that lives outside the country and they are spread all over the world [3, 19, 20].

According to statistics reported by the Ministry of Foreign Affairs from the total number of the Romanians that lives outside the borders in Italy lives 1.206.938 people which means that around 25% are located in the country that has the largest outbreak of the pandemic, and around 19% lives and works in Spain. This is the reason why Spain has become the second deadliest hotspot for COVID-19 after Italy with 27.967 cases and its death toll reached 24.824 on 1st of May 2020 [19, 20].

Having Italy as a “model “of how fast the virus spread among the citizens, medical stuff and hospitals and that no real actions were made until the spread was out of control, Romania introduced lockdown measures at an early stage in the outbreak: cancelled almost all flights in and out of the country, starting with the ones from the red zone, authorities were also quick to close bars, restaurants, cinemas and schools. Police were urging people to stay at home [19, 20].

The representatives of the Intersectoral Committee for the Prevention and Limitation of Diseases with the New Coronavirus (COVID-19), together with the representatives of the authorities responsible for this field, held a teleconference on the evening of February 22, 2020, taking into account the evolution of cases in Italy areas where many Romanian citizens are or traveling from [19].

After this point the public health authorities included persons arriving in Romania from the affected localities in the Veneto region and the province of Lodi / Lombardy or who have traveled to these localities in the last 14 days, in the category of those who must stay in quarantine for 14 days after entering the country. These measures were similar to those applied by the Italian authorities. At the same time, upon arrival in Romania, all asymptomatic passengers from the affected areas, respectively Hubei (China) or from 11 regions of Italy will be sent to quarantine for a period of 14 days [1, 2, 19].

New measures were sent by the Ministry of Health to the health units and family doctors, through the county and Bucharest public health directorates which included [21]:

- measures to control and prevent infection with the new coronavirus at land, sea / river and air border crossings. The Ministry of Health provided the necessary medical staff at the border crossing points, with specialists from the public health directorates, including by secondment from other counties and health units;
- all persons, who fall within the definition of a suspicious case, should be reported immediately by all health units where they appear (emergency units, hospitals, family doctors) to the public health departments and the Monitoring Service within Emergency Situation Department (DSU);
- Ministry of Health completed the legislative framework with necessary measures for quarantine and for the management of suspected and confirmed cases of coronavirus infection (COVID-19);
- public information campaign on the new coronavirus infection;
- individual and collective prevention measures were taken and extended with a daily information bulletin on the evolution of the situation at international level and any additional measures taken by the Romanian authorities;

Also, on March 10, 2020 the Ministry of Health operationalized the Operational Coordination Center, a unit that establishes in operational time the connection with the public health directorates and health units under the Ministry of Health subordination, to identify in real time the risk situations associated with COVID 19 infection and to establish measures that are required [20, 21].

The Operational Center had to provide up-to-date information and all the useful and vital information to establish the correct measures for the epidemic phases, real time stocks of medicines, medical equipment and disinfectants existing at national level in hospital units, the number of medical staff involved in the actions in order to limit the spread of infection, the number of free beds in infectious disease departments and Intesive Care Units [21].

Other important measure was to limit the scheduled hospitalizations in the hospitals coordinated by the Ministry of Health, in relation to the degree of bed occupancy (including ICU beds) and the local epidemiological evolution corroborated with daily report the situation of bed occupancy of the hospitals in the centralized electronic system of the Coordination Center. This measure was necessary both to ensure the capacity of hospitals to take over cases and to manage material and human resources correctly and efficiently [21].

Adequate public communication was ensured so that, during this period, the public could turn to hospitals only for emergencies. The aim was to avoid congestion in the sanitary units [21]. At that point was established a support network for infectious disease hospitals depending on the contagiousness of non-coronavirus cases. These hospitals are going to be support hospitals, in which patients will be transferred from the Infectious Diseases Hospital. In a first phase, was recommended that the support hospitals not be represented by the important emergency hospitals in the area, which can provide medical assistance for the other medical-surgical emergencies [21].

The Ministry of Health Plan also provides measures in case of extend of the crisis and in case of capacity exceed of Infectious Diseases Hospitals, as well regulations on the use of protective equipment [21].

On March 11, 2020 at the proposal of the Ministry of Health, the National Committee for Special Emergency Situations issued an order for including the temporary suspension, for a period of 6 months, of distribution, outside Romania, of medicines, medical devices and sanitary materials essential in prevention and treatment conditions associated with COVID-19 infection [21].

This measure is part of the action plan of the Ministry of Health which aims to provide adequate and continuous stocks of medicines, medical devices and essential medical materials in this situation. The list was going to be established together with the experts from the specialized commissions of the ministry, taking into account in particular, medicines such as: antivirals, anti-inflammatory, antibiotics, antipyretics, antifungals, anesthetics, sedatives, as well as other medicines considered necessary in the treatment of cases of COVID-19 and their complications [21].

The list also included medical supplies and medical devices such as overalls, gloves, syringes, masks, goggles, disinfectant solutions, as well as other medical supplies and devices identified as necessary for the management of COVID-19 cases [21].

The Centre for Supervision and Control of Transmissible Diseases issued recommendations which were published on 12 March 2020 [21].

- The preventive measures considered as most effective include: frequent hygiene of the hands with hydro-alcoholic substances through friction if hands are not visibly dirty, or with water and soap if the hands are dirty; avoid touching eyes, nose and mouth; practice respiratory hygiene by coughing or sneezing in the elbow, or use napkin/tissues and throw it away immediately; wearing a mask if the person has respiratory symptoms and ensuring in such case the hygiene of the hands after removing the mask; maintain the social distance of minimum 1 meter from the persons with respiratory diseases.

- Protective Personal Equipment (PPE) must be used based on exposure risk and based on the dynamic of transmitting the pathogen agent. The overall use of PPE will have a supplementary impact on the lack of supplies of PPE.

- The state office mentions that for the people with no symptoms, it is not recommended to use masks of any type. The wearing of the masks when it is not recommended can cause useless costs, a burden on purchases and can create a false feeling of security that can lead to the neglect of other essential prevention measures.

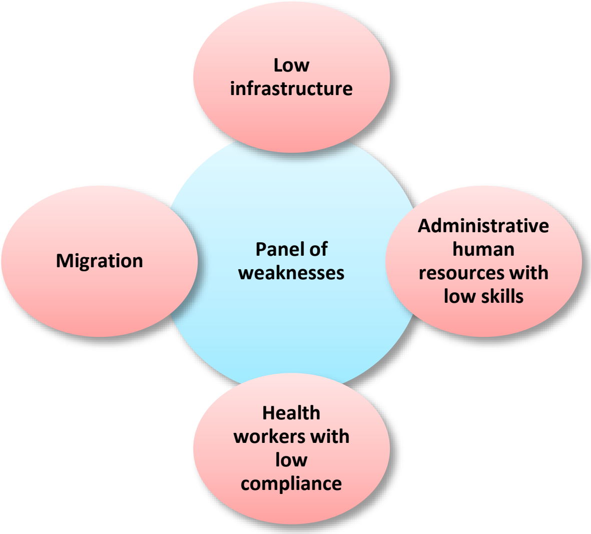
Threats and weaknesses

In order to analyze the response to COVID-19 outbreak, we identify a panel of weaknesses which conduct in early stage to quick spread of the virus and generate uncontrolled local outbreaks:

A panel of negative elements should be considered when we analyze the Romanian Health System response to outbreak.

- Low infrastructure in term of hospitals, circuits, Intensive Care Units and number of available PPE for health workers

- Administrative human resources with lack of management skills, unable to generate procedures and coordinates the Public Health Departments



Low infrastructure
Migration
Panel of weaknesses
Administrative human resources with low skills
Health workers with low compliance

Figure 5: Panel of weaknesses regarding response to COVID-19 outbreak

- Health workers with low compliance at medical information and epidemiologic resources, unwilling in many situations to respect the new statement measures and legislation provided by Ministry of Health and National Health Institute

- Not as a last item, migration, the return of Romanian citizens from pandemic areas of Europe crossing the borders using in many situations false document of false declaration and being extremely low compliant of rules and measures, regarding quarantine or in self isolation

Ministry of Health strategy

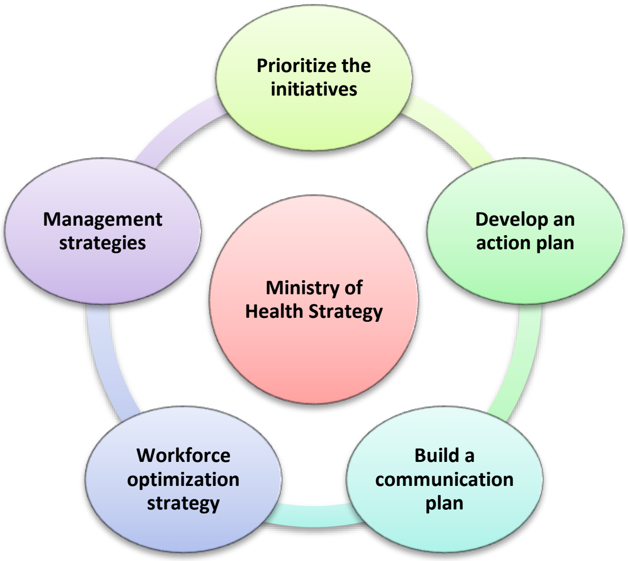
Despite those negative elements a proper and relatively quick response of Public Health System and it could say that the taken measures were harmonize and synchronize with the European coordinates. Romanian Government through Ministry of Health established 5 directions as a strategy which enhanced the national response to COVID-19 disease.

When "everything is vital and important", Ministry of Health and the other public institution involved in fighting the pandemic had to prioritize the initiatives. In order to do that a Plan of measures for the preparation of hospitals in the context of the COVID-19 Coronavirus epidemic was approved. This plan was the base of the strategy framework regarding the hospitals that can treat patients infected with COVID19. In collaboration with the local public administration authorities, based on the local analysis of patient care capacities, was generated and approved the List of support hospitals for COVID - 19 positive patients requiring treatment for specific pathologies (eg heart disease, orthopedics, etc.)

Thus, a number of 57 hospitals/outpatient departments/ buildings, 44 maternity hospitals, 60 hospitals and centers for performing dialysis procedures in all counties of the country and Bucharest were identified and designated as support units.

Supportive cases of COVID 19 that require medical care for other pathologies are also treated in support hospitals.

As a first step, designated support hospitals are non-emergency medical units that can provide medical care for other medical and surgical emergencies. Included in the network of support hospitals, municipal/city units and hospitals in other counties mainly those with Infectious Diseases departments, as well as hospitals in other networks than the Ministry of Health (Ministry of Transport, Ministry of National Defense, private health units).



Prioritize the initiatives
Develop an action plan
Build a communication plan
Workforce optimization strategy
Management strategies
Ministry of Health Strategy

Figure 6: Romanian Ministry of Health direction strategy

"The plan of measures for the preparation of the hospitals was elaborated by the specialists within the specialized commissions ICU, infectious diseases and specialists within the Ministry of Health, based on the recommendations of the WHO and EC. I asked the managers of the health units, but also the public health departments, the ambulance services to inform the medical and auxiliary staff, repeatedly, the procedures to be followed in this crisis situation, all the existing measures in the plan of measures, especially the regulations. regarding the prevention measures and the correct use, depending on the exposure, of the medical staff, but also of the auxiliary" [21].

Also, all health units from public and private system have the obligation to ensure the provision of medical care to all patients, in accordance with the disposition of the approved plan of measures. Any refusal to ensure the provision of medical care according to the specific attributions it's going to be sanctioned according to the legal disposals [21].

Develop an action plan

In order to be able to control and establish the right measures Ministry of Health with the help of the Operational Center were able to collect in real time the stocks of medicines, medical equipment and disinfectants existing at national level from the hospitals, the number of medical staff involved and the number of free beds in infectious disease departments and Intensive Care Units.

As we could see the plan is to deliver the equipment or medication where is most needed, or to purchase the equipment or medication where is most needed.

In order to simplify the Purchases of materials, medicines and equipment necessary to combat the COVID-19 pandemic, during the state of emergency, are made directly by the central and local public authorities, the legal entities in which the state is the majority shareholder, the public health directorates, the health units, as well as the National Administration of Penitentiaries and the units subordinated based on the obligation to draw up a note justifying the necessity of the acquisition.

Regulations have been approved on the use of personal protective equipment (PPE) at the level of the health unit, rationally and correctly, depending on the department, staff and type of activity. Thus, in the context of COVID-19, personal protective equipment should be used based on the risk of exposure (eg type of activity) and the transmission dynamics of the pathogen (eg contact, drops or aerosols).

The type of PPE used when caring for patients with COVID-19 will vary depending on the situation, healthcare staff and work carried out. Medical personnel involved in the direct care of patients should use the following PPE: gowns, gloves, mask and eye protection (goggles or face shield).

Specifically, for aerosol-generating procedures for patients with COVID-19 (eg: intubation, noninvasive ventilation, tracheostomy, cardiopulmonary resuscitation, manual ventilation before intubation, bronchoscopy, gastroscopy, and COVID PCR testing) medical personnel should use as protection, gloves, gowns, masks FFP2 and FFP3; waterproof aprons will also be used if overalls/gowns are not waterproof.

Build a communication plan

Creating a communication plan to collect key information from stakeholders regarding the planned initiatives and the capacity building was an important step in order to manage media coverage of the topics related to the new coronavirus infection.

Therefore, by the Decision of the National Committee for Special Emergency Situations no. 2 from February 24 2020 The Strategic Communication Group was established and it consists experts from several institutions like Ministry of Health, Ministry of Defense, Emergency Situation Department, National Institute of Public Health, General Inspectorate for Emergency Situations.

In order to support the population a Free Direct Line (Telverde) has become operational for coronavirus information in coordination of National Institute of Public Health and people can request information on how the virus manifests itself, how to prevent the disease and other details related to preventive behavior. However, the experts informed the populations that if they have any health problems or suspect that you may be infected, to continue to call the emergency number.

Workforce optimizations strategies

The evolution of the epidemiological situation determined by the spread of coronavirus on the Romanian territory, as well as the declaration of the pandemic by the World Health Organization determined the public health risk assessment for the next period as a result of the increased number of active surveillance, early detection , isolation and treatment of positive COVID 19 cases, follow-up of contacts and prevention of the continuous spread of the infection which imposes the need for additional staff involved in these activities [3, 20].

Therefore, at the proposal of the Ministry of Health, the Government of Romania approved the supplementation with 2000 positions within the county public health directorates and county ambulance services for a determined period of 6 months with 2000 positions [21].

In the current situation, the operative crews of the ambulance services are involved both in the transport of patients confirmed with COVID-19, and in the collection of samples from people in quarantine or home isolation.

Also, the staff of the public health directorates ensures the epidemiological triage from the border crossing points, monitors the self-isolated persons at home, monitors the quarantined persons, collects field samples from the persons corresponding to the case definition for testing for COVID-19.

Currently, the number of posts allocated and fully distributed by ministerial order for the county and Bucharest public health departments is 3.862, and for the county ambulance services and the Bucharest-Ilfov Ambulance Service is 11.733 posts [21].

In order to prepare the health units and the health system and the emergency system to cope in case of an exponential increase of the cases with COVID and in case of signaling a personnel deficit in some areas it was necessary to detach the health personnel to cover the needs in the area. Therefore, specialized medical staff, primary care physicians, specialists or residents, medical staff, health auxiliaries and medical staff with higher education (chemists, biologists, biochemists, physicists, pharmacists and balneo-physiotherapists) employees of public health units are about to be seconded or delegated to other public health units that have a major staff shortage.

Management strategies

The socks which make up the pandemic cause a sharp drop in consumption and investment all over the world. With the previous experiences of pandemics, governments across the world have exercised a stronger caution towards outbreak by taking early measures, such as straitening the health infrastructure to prevent the outbreak.

With the measures taken by MoH regarding the fact that many hospitals were force to close outpatient departments and postponing or canceling elective visits and procedures, it's most likely that the financial viability to be threatened, especially for those with preexisting financial challenges and those heavily reliant on revenue from outpatient and elective services.

A 2018 report from the Agency for Healthcare Research and Quality suggested that elective admissions accounted for more than 30% of total inpatient hospital revenue [22]. Elective procedures, especially orthopedic and cardiac surgical procedures, are among the most profitable services for hospitals[23]. By one estimate, hospitals earn $700 more for elective admissions than for admissions through the emergency department [24]. Furthermore, for many hospitals, outpatient revenue now equals inpatient revenue, elective or otherwise [25].

Also in Romania though reduced outpatient and elective revenue may be partially offset by higher hospital and intensive care unit occupancy during the COVID-19 pandemic, and by an increase in services after the pandemic ends, this may not mitigate losses (particularly given the need for surge personnel and resources) or be evenly distributed across hospitals.

The COVID-19 pandemic represents an unprecedented medical and economic challenge for the Romanian health care system. In the absence of robust and sustained governmental support, almost all hospitals will experience financial difficulties.

But hospitals that are smaller, independent, rural, and have critical access status are particularly at risk. Policymakers provided dedicated support to these hospitals to access funds and allocated additional funding to them during the COVID-19 pandemic.

Table 1: Global Healthcare Systems Data

Country	Australia	New Zealand	Germany	UK	US	Romania
Healthcare expenditures per capita	AU $7845 ($5,612)	NZ $5,892 ($4,015)	€4,544 ($4,924)	£2,989 ($2332)	$10,612	€1,029 ($1,115)
Medical practitioners per 1,000 people	3,94	3,35	4,3	2,8	2,6	2,8
Beds per 1,000 people	3,9	2,6	6	2,5	2,8	6,8
Population aged +60 (%)	21,4	21,3	28,2	23,8	17	22,6

Source: https://insse.ro/cms/files/publicatii/Romania_in_cifre_breviar_statistic_2018.pdf, https://www.ibisworld.com/industry-insider/coronavirus-insights/effects-of-covid-19-on-global-healthcare-systems/ [26]

According to the Medical Group Management Association, 97% of medical group practices have experienced a negative financial impact directly or indirectly related to COVID-19. On average, these practices report a 55% decrease in revenue and a 60% decrease in patient volume since the start of the COVID-19 public health emergency [20, 24, 25].

In order to evaluate if Romania can face the expenditures due to COVID-19 outbreak we tried to compare data from different global healthcare system in their heroic and unprecedented ways to meet the challenges of COVID-19.

Hospitals and health systems face catastrophic financial challenges in light of the COVID-19 pandemic. We undertook four analyses to better understand and quantify these financial challenges.

Including:

- the effect of COVID-19 hospitalizations on hospital costs;
- the effect of cancelled and forgone services, caused by COVID-19, on hospital revenue;
- the additional costs associated with purchasing needed personal protective equipment (PPE); and
- the costs of the additional support some hospitals are providing to their workers.

a) Net Financial Impact of COVID-19 Hospitalizations

At this time there are no official estimates of the net financial impact of COVID-19 hospitalizations but for the over 6,800 patients tested positive until end of April, an expense of over 77 million lei (approximate 15 million euros) is estimated by the Ministry of Health [21, 26].

Table 2: Expenditure on protective equipment against COVID-19

Equipment	LEI	Euro
Protective coveralls	50,5 mil	10,4 mil
Disposable gown	15,2 mil	3,1 mil
Disposable caps	876,000	180,000
Disposable boots	3,1 mil	653,000
Disposable sort	732,000	150,000
Disposable gloves	7,7 mil	1,6 mil
Protective eyewear	2,2 mil	453,000
Protective visors	3,1 mil	640,000
FFP2 Mask	19,4 mil	4,1 mil
FFP3 Mask	2,4 mil	510,000
Surgical Mask	36,9 mil	7,6 mil
Disinfectant	21,8 mil	3,1 mil
Total	**153,9 mil**	**32,5 mil**

Source: Ministry of Health data collection from territory 30 April, 2020[27]

b) Total Revenue Losses from Cancelled Surgeries and Other Services

As a result of cancelled hospital services due to the COVID-19 pandemic, hospitals stand to lose approximately $200 million lei (approximate 40 million euros) in revenue over a period of four months, from March to end of April 2020. This includes cancelled surgeries, various levels of cancelled non-elective surgeries and outpatient treatment, and reduced emergency department services [26].

c) Additional Costs Associated with Purchasing Needed PPE

In order to estimate future expenditures and budget allocation Ministry of Health is collecting regularly data from territory regarding the consumption and demand for equipment and supplies, such as PPE, which considerably increased as a result of the COVID-19 pandemic. Hospitals have incurred additional costs as they struggle to acquire additional supplies to meet the needs of their patients and staff. Moreover, current guidelines require all hospital workers to wear some PPE, regardless of whether they are in direct contact with COVID-19 patients. These guidelines increase the need and expense for PPE relative to normal operations.

d) Costs of Additional Support Some Hospitals are Providing to their Front-line Workers

The govern could not yet estimate the cost of support for front-line hospital workers in COVID-19 hotspots for costs of providing child care, housing, transportation, and medical screening and treatment for COVID-19 for front-line workers but measures were taken to provide such services for them [27].

This report attempts to quantify these effects over the short-term, which are limited to the impacts over a two-month period from March 1, 2020 to April 30, 2020.

Although the government moved quickly to provide relief and the budget expenditures was increase by 2,5 billion euros in order to fight the financial impact, more help is needed [26, 27].

This includes:

- 120 million euros were added in staff costs, and this includes the payment of the risk incentive of 500 euros gross per month for doctors, medical staff, paramedical staff, including auxiliary staff directly involved during the emergency.
- Social security expenditures from National House increased by over 1,4 billion euros (technical unemployment and other health expenditures).
- Expenditures on the reserve fund increase by 3 billion lei.
- The Ministry of Labor also receives 1,6 billion euros and the Ministry of Health 785 million euros.

Following the immediate measures and reallocations of the government, the Ministry of European Funds obtained following the negotiations with the European Commission, a package worth 1.16 billion euros, European funds that will be injected urgently into the Romanian medical system to contribute to the socio-economic measures taken by the Government during this period [15, 16, 26, 27].

The allocation is going to cover expenditures as following [15, 16, 26, 27]:

- 100 million euros reimbursement of the risk incentive of 500 euros gross per month for doctors, medical staff, paramedical staff, including auxiliary staff directly involved during the emergency;

- 350 million euros for reimbursements of the purchases of medical equipment (ventilators, injectors, COVID-19 tests, etc.) and protective equipment (masks, gloves, coveralls, etc.), with the possibility of increasing the allocation to 500 million.

- 682 million euros for the purchase of medical equipment and equipment for the coordination system of the national emergency system, by financing an IGSU project.

The World Bank has allocated more than $1.4 billion to support the efforts of European and Central Asian countries to combat the effects of the COVID-19 pandemic. As of April 2, 2020, it has been approved to allocate approximately $ 490 million to be distributed for new emergency response programs [15,16]. In addition, it was decided to reallocate approximately $ 925 million, which will be redistributed from existing projects and loans, as well as additional funding, to support countries working to combat the effects of the COVID-19 pandemic [15]. Ministry of Health has purchased equipment for medical protection and treatment to fight against COVID worth 29 million euros from projects financed by the World Bank in Romania [27].

CONCLUSIONS

Global shock needs global response, with little or no government interventions, economic costs will be huge. For decrease negative impact, Government spending should be as large as the predicted economic costs, focusing directly on cash disbursement to firms and households. Central banks should support financial the government, not just through their own reserves but also by printing money if necessary. It is clear state that no country has fiscal capacity to stand alone [28].

Government priority should be on health expenditure but as the specialist anticipated is mandatory to generate a strategy to flatten the contagion curve that may rise back in the end of 2020. The tasks of test ‘at random’ representative samples of the population to identify the most contagious groups and isolate immediately the more vulnerable (e.g. the old) should be in front of strategy. A global expand of intensive care capacity (both beds and equipment) by building new units or convert available other type of buildings (e.g. hotel, barracks, etc.) is needed. Another imperative measures is to relocate patient who need intensive care to non COVID hospitals in order to increase capacity of that one placed in concentrated aria of contagion in terms of human resources and infrastructure.

Romania has harmonized with WHO and European Union requirements regarding preventive measures and legislation for COVID-19 disease and show a major and continuous concern in increasing testing capacity although the number of experts in that field was decreasing year by year. Despite the major weaknesses Ministry of Health adopted the best measures in order to combat the negative impact of pandemic. A perfect management strategy was setup in local outbreaks areas, introducing military management in hospitals in which wrong management decision were taken in early stage of COVID-19 disease.

Ministry of Health registered an extremely rapid reaction in support healthcare workers, purchase medical equipment and ventilators challenging the other health systems that faced with the same health problem forcing in a positive manner Public Health System for a simultaneous high inflow of SARS-CoV-2 positive patient in terms of human resources and infrastructure (mobile hospitals for patient with no and mild symptomatology, intensive care units etc.).

As part of European Nation, Romanian Government realized the harmonization of institution using emergency state providing this way an outstanding panel of experts in critical domains which initiate the best decision in a proper time, find the measures and optimal solutions for access to European available funds, cover the huge economic cost, helping Health System to fight against a complete new disease and providing the support for return of citizens in respect of European laws and Human Rights Declaration.

CLINICAL PRACTICE

Cross-leg limb salvage solution: A case report regarding the management of a major defect in a patient with type IIIB open distal tibial fracture

M. Turbatu, C. Condrea, A. Oproiu, A. Cursaru, A. Lupu

Abstract: *Tissue coverage of lower limb defects after tibial fractures remain one of the hardest areas for a surgeon to deal with. The definitive management of Gustillo type IIIB fractures depends on a series of factors, which have a high impact in the multidisciplinary management of this severe trauma.*

Although free flaps have been used succesfully in the last two decades, there remains some cases where easier plasties using the contralateral limb tissue reserved could be indicated.

We describe our experience with a cross-leg flap in a severe-smoking patient for the reconstruction of a difficult leg defect.

Keywords: *Cross-leg plasty, Type IIIB fractures, External fixators*

INTRODUCTION

The tibia is reported to be the most commonly fractured long bone in the human body. Gustilo-Anderson IIIB injuries are a major trauma requiring aggressive excision, adequate fixation, and good coverage of tissue defects. They are open tibial fractures more difficult to manage than other I, II, and III A forms.

Stable skeletal fixation with immediate soft tissue cover has been the key to the optimal results in treating open tibial fractures, in particular, type IIIB fractures. The prognosis of these fractures depends on the degree of contamination of the wound, the devitalization of the soft tissue and area of the defect.

Pedicled cross-extremity flaps for calves wound coverage have been replaced by free tissue transfer in the last two decades. However, there are certain difficult situations where the free flap cannot be employed and alternative methods are needed.

University Emergency Hospital Bucharest, Plastic surgery and Orthopaedics, Bucharest, Romania

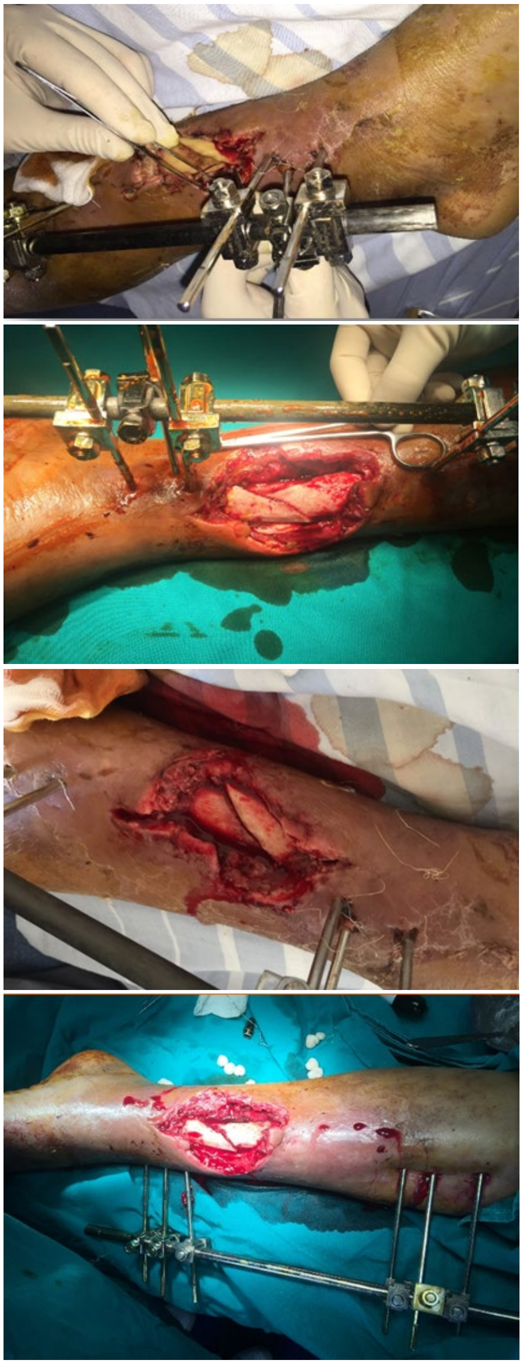
We describe our experience with a cross-leg gastrocnemius flap in a heavy-smoker patient with little tissue reserve necessary for the coverage of a defect in the middle to lower third anterior calf.

CASE PRESENTATION

We present the case of 58 years old patient who was admitted in the Orthopedics and Traumatology Clinic of the Emergency University Hospital of Bucharest with an injury after a direct trauma by axe and had pain in the calf, functional impotence of the inferior member and an open wound of about 10 cm on the inner side in the 1/3 middle anterior calf.

Following wound debridement (including post-debridement measurement) and skeletal fixation, the anterior defect was assessed [1].

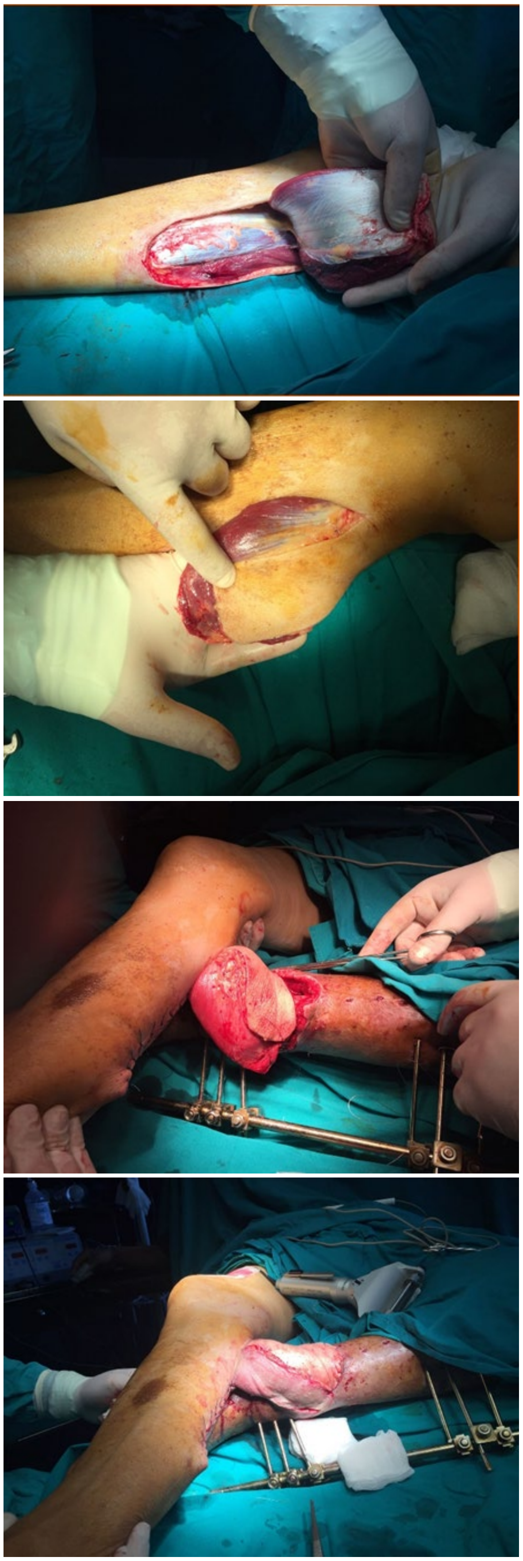
The following days the patient underwent antibiotherapy and careful daily wound dressing until a proper defect coverage plan was decided.

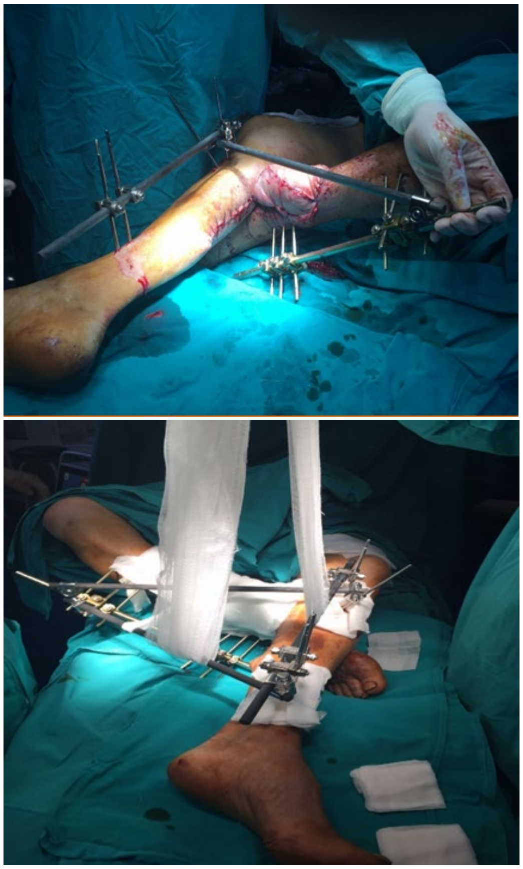


Free flaps are usually the first choice for soft tissue coverage in the distal leg. There continue to be, however, some clinical situations in which local fasciocutaneous and myocutaneous flaps are often not available [2].

Occasionally, a free flap may also have failed because of technical errors or damaged vasculature. In these situations, a cross-leg flap is the best choice.

In the end we decided to perform a pedicled cross-leg gasctrocnemius flap, with the utilization of an external fixator to keep both legs immobilized after the surgery.



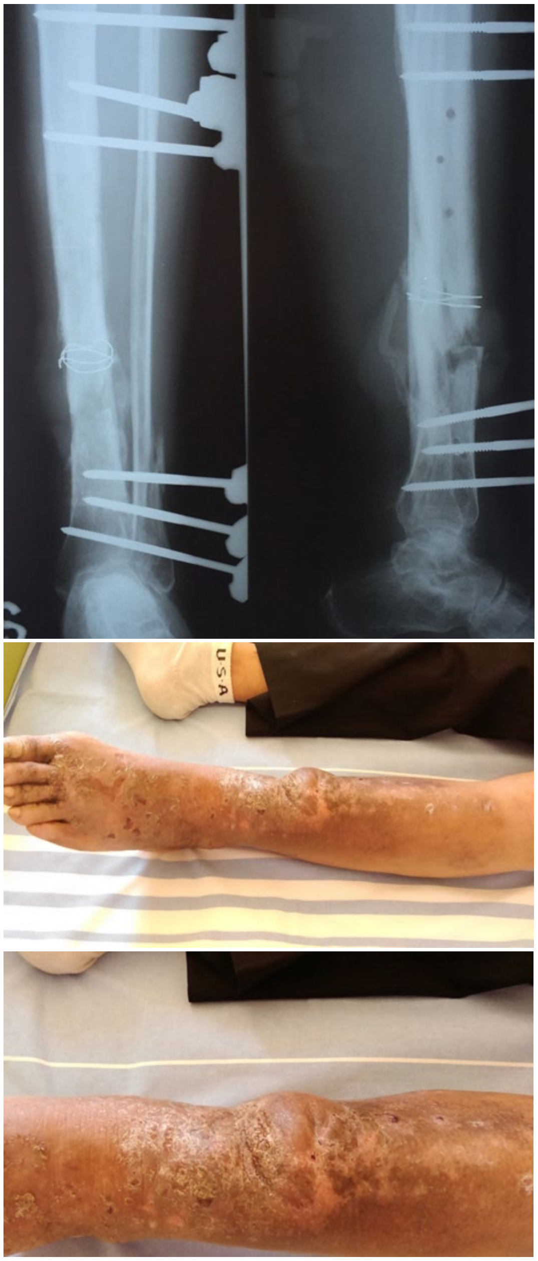


After proper preoperative markings, the flap was raised including the fascia. The inclusion of fascia in the flap makes the length-to-breadth ratio 3: 1 perfectly safe [3]. This allows much greater area of skin to be transferred with much more freedom of leg position. The donor site was covered using direct sutures and a split skin graft was also used to cover the donor muscle flap [4].

OUTCOME AND FOLLOW-UP

The release of the flap was performed at 21 days and the unaffected contralateral member was removed from fixation [5]. The patient continued treatment by monoplane external fixation for 8 weeks with progressive mobilization with the support of the unaffected limb. The patient evolution was satisfactory also making regular X-rays checks for the consolidation of the fracture.

At 4 months after the trauma, the ablation of the external fixation [6] was decided and the patient resumed progressive mobilization of both lower limbs. With the presence of the consolidated fracture, at 4 months postoperatively the patient successfully achieved a score of 62 according to Clinical rating system for the ankle and hindfoot [7].



CONCLUSION

The cross-leg Filatov flap is still considered a safer and more reliable solution to free tissue transfer in certain situations of lower-limb trauma, especially open distal tibial fractures in which rotation flaps are not a viable solution.

Crude venom of *Pseudocerastes persicus* snake: From the antibacterial to anticancer effects

Majid M. Nodooshan[1], Hossein Sobati[2], Ehsan Malekara[1], Hamid R. Goodarzi[3], Firouz Ebrahimi[4], Ashkan Normohamadi[4], Jamil Zargan[4]

Abstract: *Antibiotic resistance has been reported as one of the world's most critical public health problems.*

Recent investigations have demonstrated that the venom of some species of snakes has antimicrobial and anticancer activities. The purpose of this study was to examine the antibacterial activity of Persian horned viper venom toward Escherichia coli, Bacillus subtilis, and Staphylococcus aureus bacteria and also investigate antitumor effects of concentrations of venom with higher antibacterial activity in a human hepatocellular liver carcinoma cell line (HepG2) to evaluate the potential use of its components as antimicrobial and anticancer agents. Bactericidal activity of crude venom in concentrations of 6.25-400 µg/ml was performed using MTT reduction, minimum inhibitory concentration (MIC), agar-well diffusion, and disc diffusion methods. Tetracycline (50 µg/ml) was used as a standard antibiotic. Cytotoxic effect in HepG2 cells was measured by MTT reduction assay and confirmed with neutral uptake assay following exposure of cells with different concentrations of venom (50-400 µg/ml). The apoptotic effect was investigated using the comet assay. Our findings demonstrated that venom displays higher inhibitory effects against Gram-positive bacteria as compared to Gram-negative. Furthermore, venom showed anticancer activity on the HepG2 cell line through induction of apoptosis and necrosis. The results of this study confirmed that the venom of Persian horned viper induces antibacterial and anticancer effects. These properties make the venom of this viper a potential source for isolation of effective molecule(s) having antibacterial and antitumor activity.

Keywords: *Pseudocerastes persicus, Antibacterial, Cytotoxicity, Snake venom, anti Cancer*

INTRODUCTION

In the world of pharmacology, along with the discovery and use of new antibiotics, pathogenic bacteria also have features that are gradually resistant to them. This has always been a problem for microbiologists, a constant research field for researchers to discover more effective and newer chemical antibiotics as well as antimicrobials derived from natural sources such as toxic plants and animals, including snakes (Park et al., 2012). Studies have shown that some of the active compounds in venomous animals are an important source for the separation of effective drug substances, some of which are naturally capable of destroying bacteria (Harvey and Robertson, 2004; Koh et al., 2006). Snake venom is a mixture of various biological substances, including various proteins with enzymatic and non-enzymatic properties (Chellapandi and Jebakumar,

2008) which generally contain neurovenom, proteolytic, coagulant, phospholipase, cholinesterase, hyaluronidase, amino acid oxidase, and other enzymes (Sachidananda et al., 2007). Studies show that the effective ingredients in oral saliva or venomous snakes have long been considered by researchers and pharmacists for the treatment of some diseases, the production of various drugs, serums, and vaccines (Kuhn-Nentwig, 2003). The first reports of antibacterial activity in the venomous snakes of the family of Alpideh and Vipride in 1948 and 1968 were published (Ferreira, 1965) and Skarns also reported antimicrobial activity of some enzymes in Snake in 1970 for the first time (Aloof-Hirsch et al., 1968). Subsequently, many studies have been done about the presence of antibacterial agents in the venom of different species of snakes, which caused the isolation of some antibacterial peptides from them. Also, reports show that some of the molecules in the venoms of snakes have anti-tumor activity and prevent the growth and proliferation of cancer cells (Latifi, 2000). Chalmette's first study in 1933 examined the use of snake venom for the treatment of cancer in laboratory animals. It has introduced the results of snake venoms as an important natural source for the isolation and identification of effective molecules in the treatment of sudden illnesses like cancer in the world of pharmacology (Latifi, 2000). Pseudocerastes persicus snake is one of the most dangerous venomous snakes and a member of the Viperidae family. In addition to Iran, this Pseudocerastes persicus snake has been reported from Pakistan, Afghanistan, Oman, and Iraq, and in Iran, in the sandy, rocky and volcanic areas of Yazd, Khorasan, Kerman, Sistan and Baluchestan, Isfahan, Fars, Semnan, Central, Khuzestan, Zanjan, Tehran, Qom, and Hormozgan (Latifi, 2000). This study aimed to investigate the effect of Pseudocerastes persicus snake venom on the growth of gram-positive and negative bacteria and also the effect of probable concentrations of antibacterial effects of Pseudocerastes persicus snake venom on the growth of liver cancer cells in vitro conditions for evaluating the possibility of isolation of antibacterial and anti-cancer component.

MATERIALS AND METHODS

Venom Preparation and Protein content determination

To prepare the venom from the vein, while observing the safety considerations and placing its toxic teeth inside the glass of venom collection, and with brief pressurization to the toxic glands of the viper, the venom contained in them was injected into the glass (Lu et al., 2002). The lyophilized solution was stored and kept until it was used in experiments at -20°C. To carry out antibacterial tests, some of the venoms were pulverized in 250 µl of 50 mM sterile tris hydrochloride buffer, and a few of the venom was mixed in 150 µl water twice per sterilized distillation. The amount of protein in the homogenized toxic solution was determined using the Bradford method (Bradford 1976) at 595 nm (Bradford, 1976). To eliminate potential microbial contamination in the venom solution, the required 1% antibiotic-anti-smectic antibody (Antibiotic-Antimycotic: Invitrogen, USA) is required, and after one night at 4°C was used in experiments.

The bacteria and cell line used

Gram-positive bacteria Bacillus subtilis (nonpathogenic) (Bacillus subtilis subsp. spizizenii, ATCC 6633), gram-negative bacteria of Escherichia coli (ATCC 25922 Escherichia coli), and gram-positive strain of Staphylococcus aureus (pathogenic)(ATCC 25923) from the collection center of Persian Type Culture Collection (PTCC) and liver cancer cells (HepG2) were developed and used from the cell bank of Pasteur Institute of Tehran.

Antibacterial properties of crude venom

Culture media and antibiotics: For a culture of bacteria used from liquid and solid Mueller Hinton (MH) and for comparing the toxic effect of venom with a standard antibiotic used from tetracycline (Sigma, USA) at a concentration of 50 µg/ml.

MTT assay

MTT test is a colorimetric method based on the regeneration and breakdown of tetrazolium yellow crystals by the enzyme succinate dehydrogenase present in the cytoplasm and eventually the formation of insoluble blue crystals. These crystals are dissolved by adding DMSO (Wang et al., 2010). Test microorganisms were grown in MH broth for 5 h (exponential phase) and adjusted to 0.5 McFarland turbidity standard (A600 = 1.0), corresponding to 1.5×106 cfu/ml (Yalcın et al., 2014), 5µl was added in sterile plate 96-wells. Also, the final volume of each well was measured using a liquid culture medium (MH Broth) to 100µl using serial dilution. The bacteria were contacted at concentrations of 6.25, 12.5, 25, 50, 100, 200, and 400µg/ml of crude venom. In this experiment, tetracycline (50µg/ml) as a positive control, a culture medium containing bacteria as negative control, and a non-bacterial culture medium was used as blank. The plate was incubated for 23 hours at 37°C. Then, 5µl MTT (concentration 5µg/ml) was added to all wells and placed in dark conditions at 37°C for one hour. Then, 100µl of DMSO was added to each well. After 2 hours of incubation in dark conditions, the optical absorption of wells at 595 nm was measured using a plate reader (Biotek, USA). The above experiment was performed 3 times and at each time 3 wells (3 repetitions) were considered for each concentration. The percentage of bacterial survival after contact with different concentrations of the venom was calculated using the following formula (Yalcın et al., 2014).

Bacterial vital percent:

Viable Bacterial = (a/b) ×100
a = Optical Absorption Sample - Blank Optical Absorption
b = Negative optical absorption - Blank optical absorption

Minimum Inhibitory Concentration Test (MIC)

The steps of performing the minimum inhibitory test on plate 96-well were similar to the MTT assay but after placing the bacterium in a culture medium containing different concentrations of venom and incubating them for 24 hours at 37°C without adding any marker. Also, the absorbance of wells at 605 nm was measured using a plate reader (Biotek, USA). This experiment was repeated 3 times and at each concentration 3 wells (3 repetitions) were considered for each concentration. The inhibitory percentages of the effect of venom and standard antibiotics on the tested bacteria were calculated using the following formula (Shebl et al., 2012).

Percentage of inhibition of bacteria = [1-(a/b)]×100
a = Optical Absorption Sample - Blank Optical Absorption
b = Optical Absorption Control - Blank Optical Absorption

Disc diffusion assay

This experiment was carried out according to Bauer et al (Bauer et al., 1966).

The bacteria were first cultured in a culture medium Mueller–Hinton broth and incubated for 24 to 18 h at 37°C. A solid culture medium with a thickness of 4 mm was prepared in glass plates. 200µl of the 0.5 MacFarland suspension was placed on a plate surface and a cotton seedling was cultured using a sterile loop. Using sterile pin disks (prepared from antibacterial medicine) containing 40µl of venom in the concentration of 3.125, 6.25, 12.5, 25, 50, 100, 200, and 400 µg/ml on the surface plate was placed. In this experiment, 50µg of tetracycline antibody was used as a positive control for 50 µM tetracycline, and 50 mM Tris hydrochloride was used as a negative control. Plates were incubated for 24-18 hours at 37°C, and then an inhibition zone was determined and its size was determined. This experiment was performed 3 times for each bacterial strain.

Well diffusion assay

This method is similar to the disk diffusion method, except that in this test, the venom solution was added to the well instead of being placed on the disk (Torres et al., 2010). In summary, after the cultivation of grass, using the end of the pasteurized pipette, the wells were transferred to the medium and cut into pieces of gel, and 20µl of liquid agar medium was used to block the bottom of the well and prevent leakage and solution leakage. The venom was poured into the well under the medium. After pouring 40µl of Crude venom in concentrations of 3.125, 6.25, 12.5, 25, 50, 100, 200, and 400 µg/ml, the plate was incubated for 24 to 18 hours in an incubator at 37°C. After the mentioned time, the presence of a halo around the wells was investigated and its diameter was determined. This experiment was performed 3 times for each bacterial strain in two replicates.

Evaluation of anti-cancer properties of crude venom

Cell culture

Liver cancer cell line (HepG2) was cultured using DMEM-F12 (Gibco, USA) containing 10% Fetal Bovine Serum (Gibco, USA). These cells were cultured in flasks of 25-50 ml cubic meters and stored at 37°C and 5% carbon dioxide. Replacing every 2-3 days of the culture medium and after providing the cell population required for each test, using a Trypsin-EDTA prepared from Sigma-Aldrich, the USA from a flask and after counting using a Neobar lam were placed.

MTT reduction assay

This experiment was carried out according to the method performed by Zargan et al. (Zargan et al., 2011). To perform this test, 3×104 cells/well were plated in 96 wells containing 100µl of non-serum culture media. After overnight incubation at 5% CO_2, moisture content of about 80% and temperature of 37°C were removed outside the culture medium and the cancerous cell was exposed to a new culture medium (lacking serum) containing different concentrations of venom (50, 100, 200 and 400µg/ml). After 24 hours, 5µl of MTT solution (concentration 5mg/ml) was added to each well. After the formation of crystalline (formalin) in living cells, the culture medium of each well was removed and after washing in the well with PBS, 100µl of DMSO was added. After 4 to 3 hours of incubation in dark conditions and dissolving purple crystals in DMSO, the optical absorption of wells at 570 nm was measured using a plate reader (Biotek, USA). In this essay, the culture media was used as a blank and control medium containing the cells as control. This experiment was repeated 3 times, and 3 wells (3 repetitions) were considered for each concentration. The percent survival of the cell after contact with different concentrations of the venom was calculated using the following formula (Shebl et al., 2012).

% Viable cell = (a/b) × 100
a = the absorbance of treated cells - the absorbance of the blank

b = the absorbance of the control - the absorbance of the blank

Cytotoxicity study by Neutral Red Uptake Assay

The steps of performing a neutral color red color test (Waheed et al., 2013) were similar to the MTT assay, but after incubating the cell with a toxic solution for 24 hours, a microplate of neutral red solution (5 mg/ml) instead of MTT was added to each well. After binding of neutral red matter to the lysosome surface of the living cell and the formation of red crystals in the living cytoplasm, the culture medium containing the neutral red of each well washed and after washing twice with each PBS, 100 µl of fixative buffer (37% formaldehyde, Calcium chloride (10%) was added. After one minute, the buffer was removed and 100µl of solvent buffer (0.5% acetic acid) was added. The plate was measured on a shaker for twenty minutes under microwave conditions and incubated at lab temperature and absorbed by wells at a wavelength of 540 nm using a plate reader (Biotek, USA). This experiment was repeated 3 times, and 3 wells (3 repetitions) were considered for each concentration at each concentration. The mortality rate due to different concentrations of venom on cell growth was calculated using the following formula.

Percentage of cell death = [1-(a/b)] ×100

a = the absorbance of treated cells - the absorbance of the blank

b = the absorbance of the control - the absorbance of the blank

Investigation of induction of apoptosis by venom using comet assay test

This test is one of the best methods for checking the damaged DNA in the cell (Sajad et al., 2013). To conduct this experiment, at first, in each well of the plate, 24 sterile wells containing 300µl of serum medium, cultured 12×104 cells. The plate was incubated overnight under conditions of 5% CO2, humidity 80%, and temperature 37 ° C. In this assay, the culture media was used as a blank and control medium containing the cells as control. After that, the initial culture medium of each well, evacuation, and cells was exposed to 300µl of a new culture medium (without serum) containing different concentrations of venom (50, 100, 200, and 400µg/ml).

After incubating the cell for 24 hours at 37 ° C, 80% moisture content, and 5% CO2, cells of each well were isolated using trypsin. Microtubes containing cells were evacuated for 5 minutes at 4 ° C with 1500 rpm of the centrifuge and aqueous solution. 400µl of PBS (pH = 7.4) was added to each of the tubes to wash the cells, and after centrifugation, the supernatant was evacuated. Then, 200µl of PBS was added to the tubes, and cells were separated from each other by the separate sampler and insulin syringe. Also, the slides needed for testing were coated with agarose with normal melting point (NMA% 1), test cell suspension and control with low melting point agarose (LMA% 1), one to two on the slides a flat layer was placed. To lyse the cell and nucleus membrane, all slides are placed in the refrigerator in a refrigerator buffer (NaCl 2.5M, EDTA 100mM, Tris 10mM, NaOH 0.2M, Triton X-100% 1 pH = 10) for 16-18 hours. After removing the buffer, the slides were washed for 20 minutes and 2 times with electrophoresis buffer (3M NaOH, EDTA 1mM, and pH>13), and then to open the DNA for 40 minutes in a cold electrophoresis buffer temperatures were maintained at 4°C. The slides were then extracted from the solution and placed in a buffer containing an electrophoresis tank and electrophoresed at 45°C for 45 minutes at a voltage of 25 and 300 mA. In the next step, to undo the playing environment, the slides were placed in a neutralizing buffer (Tris% 4 M, pH = 7.5) for 10 minutes. To staining cells, 100 µl of ethidium bromide solution (concentration 20 µg/ml) was added to each slide, and after 10 minutes incubated at the laboratory for 10 minutes, they were distilled twice with water. DNA of each slide cell was studied by fluorescence microscopy. For each sample, different slide positions and at least an image of hundreds of cells' DNA were prepared and the results were analyzed statistically.

Statistical analysis

The results of each test were reported as Mean±SD and the data were analyzed using software (GraphPad InStat). Different concentrations of venom were compared to the control group and compared to each other by one-way ANOVA and Tukey tests. P<0.05 was considered significant in all tests. Draw diagrams in the Microsoft Excel software (2013 version).

RESULTS

Evaluation of the Anti-Bacterial Properties of Crude venom

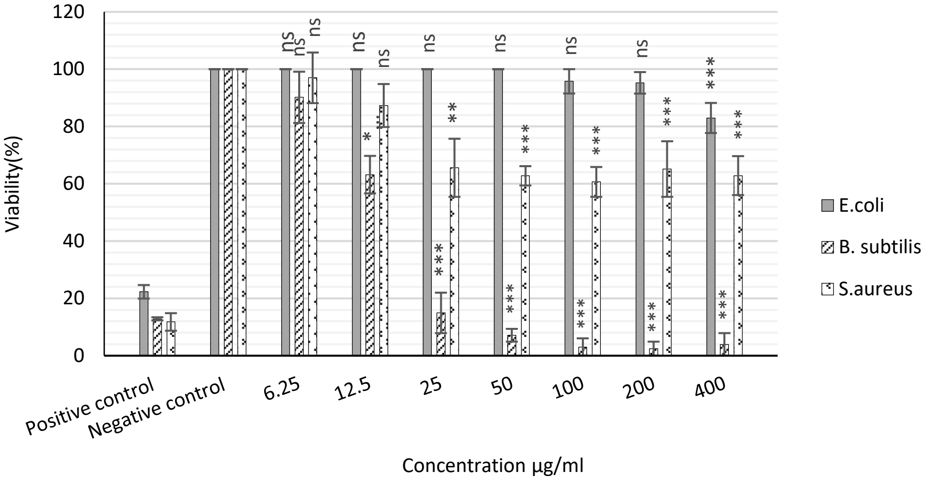
Test results MTT assay

The results showed that venom only at 400µg/ml concentration significantly inhibited the growth of Escherichia coli bacteria compared to the negative control (normal culture medium). The critical percentage of this bacterium in concentrations of 6.25-50 µg/ml was 100 and in 100, 200, 400 µg/ml concentrations respectively were 95.79, 96.29, and 83 (Figure 1).

In the case of the Bacillus subtilis strain, Crude venom in the concentration of 12.5 to 400µg/ml produced a significant inhibitory effect on bacterial growth compared to the negative control.

The percentage of vital bacteria in different concentrations of venom 6.25, 12.5, 25, 50, 100, 200 and 400 µg/ml respectively were 89.62, 62. 49, 13.73, 6.56, 2.14, 1.63 and 4.6.

Figure 1: Antibacterial effect of different concentrations of Pseudocerastes persicus snake crude venom on Escherichia coli, Bacillus subtilis, and Staphylococcus aureus using MTT assay. The effect of concentrations was evaluated in comparison with the negative control group.



(: p<0. 05), (**: p<0. 01), (***: p<0.001), (ns: non-significant).*

Venom hurt the growth of this bacterium at a concentration of 6.25µg/ml, but this effect was not significant in comparison with negative control. In the range of 25-400, the inhibitory effect of the venom was greater than the positive control (tetracycline). Statistical analysis showed that the effect of venom in a concentration of 50-400 µg/ml was significant for this bacterium but it was not significant compared to each other. According to the results, IC50 of the venom for Bacillus subtilis was determined to be 15.32µg/ml. The results also showed that the vital percentage of Staphylococcus aureus bacteria in the concentration of 6.25, 12.5, 25, 50, 100, 200, and 400µg/ml of crude venom were 95.11, 85.29, 72.48, 62.23, 59.98, 63.31, and 63.96. Crude venom at a concentration of 25-400 µg/ml produced a significant inhibitory effect on the bacteria compared with the negative control. Venom in the concentration of 12.5µg/ml hurt the growth of this bacterium, but this effect was not significant compared to negative control. Statistical analysis showed that the effect of venom in concentrations of 25-400 micrograms per ml was significantly less than the negative control, but compared with each other, it is not significant (Figure 1).

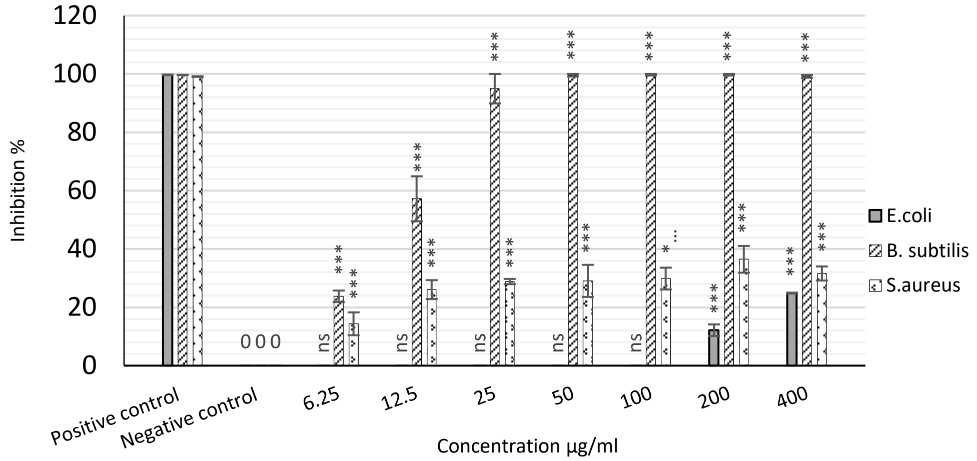
Minimum Inhibitory Concentration Test results

Pseudocerastes persicus snake venom at concentrations of 6.25-100 did not inhibit the growth of Escherichia coli, but induced inhibitory effects at concentrations of 200 and 400 µg/ml, respectively were 12.15 % and 24.99 % which, compared to the intolerance of tetracycline, and the difference in their effect is significant (Figure 2).

The inhibitory effect of venom on Bacillus subtilis bacteria in the concentrations of 6.25, 12.5, 25, 50, 100, 200, and 400 µg/ml was 23.22, 58.92, 92.80, 99.48, 99.65, 99.71, and 99.3, respectively. According to the results, the IC50 of the venom for Bacillus subtilis was determined by 10.81µg/ml. The statistical analysis showed that Crude venom at a concentration of 6.25-400 µg/ml had a significant inhibitory effect on Bacillus subtilis bacteria growth compared to the negative control. The inhibitory effect of venom was 25-400 µg/ml in comparison to the negative control, but compared with each other and in comparison with standard antibiotics was not significant (Figure 2).

Crude venom has an inhibitory effect on the growth of Staphylococcus aureus, and the inhibitory effect induced in it was 6.25, 12.5, 25, 50, 100, 200, and 400 were 13.95, 25.28, 29.13, 27.30, 30.52, 35.91, and 31.69 µg/ml, respectively. Statistical analysis showed that the toxic venom has a significant inhibitory effect on the growth of this bacterium at concentrations of 6.25-400 µg/ml, compared to the negative control. The losses caused by the effect of venom in different concentrations ranged from 25-400 µg/ml compared to the negative control but were not significant in comparison with each other (Figure 2).

Figure 2: Antibacterial effect of various concentrations of Pseudocerastes persicus snake crude venom on Escherichia coli, Bacillus subtilis, and Staphylococcus aureus using MIC assay. The effect of concentrations was evaluated in comparison with the negative control group.

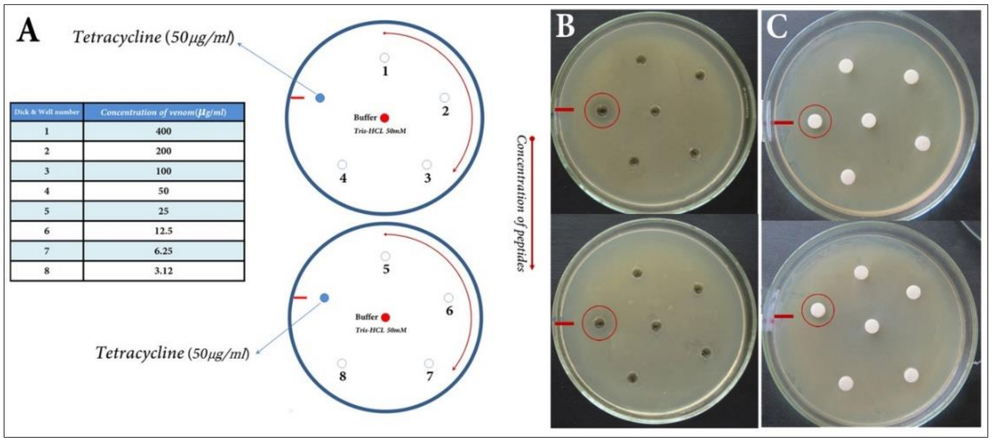


(: p<0. 05), (**: p<0. 01), (***: p<0.001), (ns: non-significant)*

Results of diffusion tests on disk and wells

The results of the effect of various concentrations of venom in the diffusion test on the disk and wells indicate that the results of these two tests, especially at low concentrations of venom, are not repeatable. However, according to the results of this study, it was found that the venom in these concentrations did not inhibit the growth of Escherichia coli (Figure 3).

Figure 3: Antibacterial effect of various concentrations of Pseudocerastes persicus snake crude venom on Escherichia coli, Bacillus subtilis, and Staphylococcus aureus using MIC assay. The effect of concentrations was evaluated in comparison with the negative control group.



The results of these experiments on Bacillus subtilis bacteria showed that the venom had an inhibitory effect on bacterial growth at a concentration of 50-400 µg/ml, but did not have an inhibitory effect on the growth of the bacteria in the concentration of 6.5- 25 µg/ml (Figure 4).

Also, venom only prevented the growth of Staphylococcus aureus at concentrations of 200 and 400 µg/ml and did not inhibit the effects of lower concentrations (Figure 5).

Evaluation of anti-cancer properties of Crude venom

Results of cytotoxicity testing by MTT method

Venom at concentrations of 50, 100, 200, and 400 µg/ml causes high mortality in liver cancer cells, respectively, in which the vital percent of the cell at the above concentrations were 14.12, 10.97, 10.43, and 9.96% has dropped. The cells losses caused by the different concentrations of venom are not significant (Figure 6).

Cytotoxicity test results with neutral red colorimetric method

The mortality rate of liver cancer cells in the concentration of 50, 100, 200, and 400 µg/ml of crude venom was 60.13, 72.58, 81.61, and 77.48 %, respectively. Venom has a significant inhibitory effect at concentrations of 100-400 µg/ml in comparison with the control (containing cell and culture media), but the mortality rate is compared between all concentrations is not significant (Figure 7).

Investigation of venom apoptosis induction using comet assay test

The results of this study showed that Pseudocerastes persicus snake venom induces apoptosis and causes mortality in liver cancer cells. Venom at concentrations of 50, 100, 200, and 400 were 36.6, 43.28, 51.5, and 47.13%, respectively, induced apoptosis in the cell. The morphological study of venomous cells also showed that the venom of this aphid, in addition to apoptosis, induces necrosis in liver cancer cells, and this effect has an upward trend of more than 200 μg/ml in comparison with lower concentrations. These results indicate that mortality in cancer cells is due to the common effects of apoptosis and venous necrosis (Figure 8).

DISCUSSION AND CONCLUSIONS

According to the World Health Organization, 40% of the 50 million annual human mortality is due to bacterial contamination and microbial diseases (Ivnitski et al., 1999). Also, bacterial infections caused by resistant strains and problems due to the lack of treatment of people with them have become an important health problem. This has led researchers to investigate more in living organisms, including various venomous snakes, to discover more effective and new antibiotics. According to studies conducted in recent years, venomous snakes are a source of unknown molecules of active substances (25) that can be considered as an appropriate candidate for the production of antimicrobial and anticancer drugs. In this study, for the first time, the antibacterial and cytotoxic effects of Pseudocerastes persicus snake were studied in vitro conditions to evaluate the possibility of isolating molecules with antibacterial and toxic effects for cancer cells. MTT reduction, MIC assay, Disc diffusion assay, and Well diffusion test were used to study the antibacterial effects of crude venom. The results obtained from MTT reduction and MIC tests showed that Pseudocerastes persicus snake venom has an inhibitory effect on Escherichia coli bacteria as a representative of gram-negative bacteria only at the highest concentration (400 µg/ml). However, bacteria Bacillus subtilis and Staphylococcus aureus have been prevented from bacterial growth at concentrations of 12.5-400 and 25-400 µg/ml, respectively. The reason for the difference in the results of MTT and MIC is due to the difference in the calculation of the inhibitory effect of the venom in two methods, in the MIC method, the opacity is due to the presence of bacteria, which includes dead and living bacteria, is measured at a wavelength of 605 nm. While in the MTT method, the optical absorption of formazone particles formed in the cytoplasm of the living bacteria is determined after dissolution in DMSO at 570 nm. MTT testing seems to provide more accurate results than the MIC method. Also, the results of the study showed the antibacterial effects of crude venom using two methods of diffusion in wells and discs. In this study, snake venom has no inhibitory effect on gram-negative bacteria but has an antibacterial effect on two-gram positive bacteria. The results showed that these two methods qualitatively confirm the effects of MTT and MIC, but did not quantitatively produce repeatable results. One of the reasons for this issue, it seems, is that the proteins and toxic peptides are deposited at the bottom of the well, and the walls and around the wells act as a filter and penetrate the entire contents of the venom into the well prevents solid culture. In the case of a disk, it is also possible that the disk itself acts as a filter and prevents the outflow and full penetration of the components of the venom into the medium. The rapid absorption of water in the upper surface of the medium using a paper disk and the lack of complete absorption of toxic compounds that allow heterogeneous release in the medium is another disadvantage of this method. In this study, it was determined that Pseudocerastes persicus snake crude venom is more effective than gram-positive bacteria. This selective antibacterial activity may be due to several factors such as the difference between bacterial species such as density and lipopolysaccharide structure present in the wall of gram-negative bacteria or fat composition in the cytoplasmic membrane and electrostatic potential across the membrane in gram-positive bacteria Be (San et al., 2010). The results of studies by Husniye et al. (2012), Shebell et al. (2012), Stabley et al. (2004), Steels et al. (1991), and similar studies show that venomous affect gram-positive bacteria (Stiles et al., 1991; Lu et al., 2002; Yalcın et al., 2014; de Lima et al., 2005; Stábeli et al., 2004). Also, the results of the antibacterial effect of Jafri's venom (Jami et al., 2011) showed that snake venom has a better effect on Staphylococcus aureus bacteria than Escherichia coli bacteria. The results obtained in this study are consistent with previously reported results regarding the antibacterial effects of snake venom. On the other hand, the inhibitory effect of Pseudocerastes persicus snake crude venom in the highest concentrations studied in this study on E. coli is an effective component of this bacterium at very low concentrations in venom. The results of studies by Chalapandi et al. (2008), Bostley et al. (2008), Starker and Trierworth in 1986, and similar studies have reported the inhibitory effects of venomous organisms on gram-negative bacteria (Chellapandi and Jebakumar, 2008; Stiles et al., 1991; Shebl et al., 2012; Bustillo et al., 2008). Snakes venom are mainly composed of proteins and peptides that have diverse biological activities. Some of these molecules have been shown to have inhibitory effects on cancer cell growth in clinical trials and may find their way toward developing anticancer drugs in the future (Jain and Kumar, 2012). In this research, the effects of toxicity of venomous snake, which has antimicrobial properties induced by the use of MTT assay, Neutral red uptake assay, and Single cell gel electrophoresis (Comet assay) on liver cancer cells (HepG2 cell line) was taken into consideration in vitro conditions. Reports on the presence of cytotoxic effects in the venom snake have led to the use of HepG2 cells in this study (Latifi, 2000). The results of the MTT assay and uptake assay showed that crude venom at concentrations of 50, 100, 200, and 400 µg/ml has cytotoxic effects and causes the death of liver cancer cells. These results are consistent with findings from Bozemans et al. (2005), Yang et al. (2006), Depeca et al. (2012), Sang et al. (2012), to induce cytotoxic properties by venoms of a snake (Jain and Kumar, 2012; Bosmans et al., 2005; Cancer Control Office, 2005; Song et al., 2012; Yang et al., 2006). As well as the results of Shebel, et al suggesting that mortality in the cell would be increased by increasing the concentration of venom (Shebl et al., 2012). To investigate the possibility of inducing cell death through crude venom through apoptosis in HepG2 cells, this study was conducted using Comet assay. The results showed that crude venom at concentrations of 50, 100, 200, and 400 µg/ml caused apoptosis in cancer cells the liver causes it to die. It was also found that with an increase in concentrations of 50 to 200 µg/ml of crude venom, apoptosis has a tendency to increase, which is consistent with previous reports (Sajad et al., 2013). Generally, the results of this study showed that the crude venom of snakes contains molecules that can have anti-bacterial and anti-cancer activity. These results suggest that the venom of a snake is a suitable candidate for the isolation, purification, and introduction of valuable drug molecules to combat antibiotic-resistant bacteria as well as anti-cancer agents.

Management of Helicobacter pylori infection – new insights

Andrei Gavrilă[1],Andrada Popescu[1], Petruț Nuță[1], Raluca S. Costache[1,2], Mariana Jinga[1,2], Săndica Bucurică[1,2], Bogdan Macadon[1], Mihăiță Pătrășescu[1], Florentina Ioniță Radu[1,3]

Abstract: *Introduction: Our objective is to review current international guidelines for Helicobacter Pylori treatment and our department`s experience in this field.*

Materials and methods: Helicobacter pylori is a Gram-negative, microaerophilic bacterium that can be found mainly in the gastric mucus or on the inner surface of the gastric epithelium, infecting up to 50% of the population. Colonization with this bacterium is not a disease in itself, but can cause chronic gastritis, peptic ulcer, gastric cancer and MALToma. Because of this, infection with H. pylori continues to be a major healthcare burden, especially in less-developed countries.

A multitude of non-invasive tests are available for the diagnosis of Helicobacter pylori infection (blood antibody, stool antigen or urea breath test), but the most reliable method of diagnosis is histological examination from two sites after endoscopic biopsy, combined with either a microbial culture or rapid urease test.

Treatment of Helicobacter pylori infection is becoming a challenge, as eradication following standard triple therapy is decreasing worldwide due to increased bacterial resistance against antibiotics, which has led to the development of newer therapies such as the sequential treatment in which a PPI and amoxicillin is given for 5 days followed by a PPI, clarithromycin and metronidazole for another 5 days, or the quadruple therapy based on a PPI, bismuth subcitrate, metronidazole and tetracycline for 10 days.

Results and conclusion: H. pylori infection remains one of the most challenging infectious diseases, causing high morbidity and mortality, mainly because none of the actual antibiotic therapies can provide successful eradication.

Keywords: Helicobacter pylori, ulcer, adenocarcinoma, antibiotics, PPI

INTRODUCTION

Helicobacter pylori (Hp) is a helix shaped, Gram-negative, microaerophilic bacterium that can be found mainly in the gastric mucus or on the inner surface of the gastric epithelium[1]. Hp infection is the most common chronic infection in humans, but colonization with this bacterium is not a disease in itself. Although most infected individuals remain asymptomatic for life, Hp is responsible for a number of pathological manifestations including chronic gastritis, gastric or duodenal ulcer, adenocarcinoma

[3]TituMaiorescuUniversity, Bucharest

of the stomach or gastric mucosa–associated lymphoid tissue (MALT) lymphoma[2].

THE DISCOVERY OF HELICOBACTER PYLORI

The Helicobacter pylori bacterium was discovered by two Australian researchers by the name of Barry Marshall and Robin Warren, who also deciphered its role in gastritis and peptic ulcer disease (PUD)[3]. Their discovery was published in 1982, at a time when it was a long-standing belief that stress and lifestyle factors were the major causes of PUD. The scientific community of the time met their findings with skepticism and a lot of criticism, refusing to belief that any life-form can survive in the acid medium of the stomach. This is why it took a very long time and effort for their discovery to become widely accepted[4].

Marshall`s 1985 “self-help” experiment rebutted the “stress and life-factors” dogma. He first underwent gastric biopsy to show the absence of the bacterium, then, to the horror of his assistant, ingested a turbid, foul-tasting solution of Hp. Soon he developed a number of symptoms including nausea and vomiting and an endoscopy with biopsy was performed, which revealed signs of gastritis and the presence of Helicobacter Pylori[3].

EPIDEMIOLOGY

Transmission of Hp is believed to be by gastro-oral or fecal-oral routes as the bacterium can be cultured from vomitus or diarrhea stools. Therefore, the overall prevalence of infection can be influenced by lack of proper sanitation and basic hygiene, of safe drinking water, as well as overcrowding, making it a public-health issue in developing countries[1].

One of the most important risk factors is childhood socioeconomic status, meaning that infection is acquired at an early age, especially in developing countries. It is common for spontaneous clearance to occur during early childhood, but the chance of reinfection is greater in developing countries compared to developed ones – where it is estimated to occur in less than 0.5% of cases per year[5].

Due to these factors, prevalence of infection can reach up to 80 % by the age of 20-30 in developing areas, whereas in developed countries prevalence is less than 20 % in individuals younger than 30 years, but can reach up to 40-50 % in those 60 of age or older[2].

PATHOPHYSIOLOGY

Clinical outcome of Hp infection is dependent on sophisticated interactions between the bacterial, host and environmental factors. In order to promote chronic infection, H. pylori first has to survive in the harsh acidic environment of the gastric medium[6]. One of the most important bacterium survival technique is the “acid acclimation mechanism” that adjusts periplasmic pH by regulating activity of urease. Another factor on which successful colonizationof the gastric epithelium depends is bacterial motility provided by the presence of 4 to 6 functional unipolar flagella. Recent studies show that peptidoglycan-degrading enzymes are necesary for the proper assembly ofthese flagella[7]. After colonization, adherence to gastric epithelial cells is necessary and this is done thanks to a variety of outer membrane proteins (OMPs), several of which can serve as adhesins, the most important being BabA and SabA. H. pylori employs genetic diversification to adapt to the host immune response and promote persistent infection[8].

This pathogen possesses various virulence factors known to be significant in the induction of disease during infection. One of the most studied effector molecule is cytotoxin-associated gene A (CagA) which is injected into the host cell upon contact via the cag pathogenicity island (cagPAI)-encoded typeIV secretion system. Once intracellular, CagA localizes on the inner surface of the celular membrane and is subjected to a tyrosine-phosphorylation process by Src family kinases. The phosphorylated CagA subsequently induces a signaling cascade, causing proinflammatory responses in epithelial cells[9]. While the literature is contradictory, some studies, including those of Kang et al. and Papadakos et al., sugest that inflamation is induced via the nuclear factor (NF)-kB signaling pathway and subsequent interleukin (IL)-8 secretion[7]. Taking this into consideration, and also the fact that CagA translocation and phosphorylation are mediated by cholesterol-rich microdomains of the plasma membrane, Lin et al. found that methylantcinate B, a triterpenoid extracted from the Antrodia camphorata mushroom, attenuates CagA translocation and phosphorylation and inhibits CagA functions, including NF-kB pathway activation and IL-8 secretion; but further in vitro research is needed to assess the possibility of a new, antibiotic-free regimen[9].

DIAGNOSIS

The diagnostic procedure of Hp infection can be difficult due to the fact that up to 80-85% of infected individuals are asymptomatic, while the rest develop a series of non-specific symptoms, such as nausea, vomiting, abdominal pain, heartburn, halitosis or diarrhea[1]. This is why specific indications for testing were stipulated. These include active or documented history of peptic-ulcer disease, early-stage gastric MALToma, early gastric cancer, or uninvestigated dyspepsia in high prevalence areas[4]. Testing for the primary prevention of gastric cancer can be performed in individuals with high risk, such as those with family history of gastric cancer, or first-generation immigrants from a region with high-incidence for this malignancy. Some physicians recommend testing prior to starting long-term non steroidal anti-inflammatory drugs or proton pump inhibitors (PPI)[10].

There is also clear evidence that Hp can be involved in the pathogenesis of some extra digestive diseases, with a clear indication to test for infection in individuals with unexplained iron-deficiency anaemia, idiopathic thrombocytopenic purpura (ITP) and vitamin B12 deficiency[11]. Other studies have tried to find a link between Hp infection and some cardiovascular, lung, hepatobiliary or neurological disorders, but failed to produce an unequivocal causative association thus far[12].

Several methods are currently available for detecting Hp infection. Unfortunately, there is no gold-standard diagnostic test due to the fact that every method has it`s limitations and disadvantages [13] (as seen in table 1).

Table 1: Diagnostic tests for Helicobacter pylori infection [14]

Endoscopic Testing	Advantages	Disadvantages
A) Histology	Excellent sensitivity and specificity	Expensive. Requires infrastructure and trained personnel
B) Rapid urease testing	Inexpensive. Provides rapid results. Excellent specificity and very good sensitivity.	Posttreatment sensitivity significantly reduced
C) Culture	Excellent specificity. Allows antibiotic sensitivities determination	Expensive. Difficult to perform. Not widely available.
D) Polymerase chain reaction (PCR)	Excellent sensitivity and specificity. Allows antibiotic sensitivities determination	Not standardized across laboratories. Not widely available
Nonendoscopic Testing	**Advantages**	**Disadvantages**
A) Antibody testing (quantitative and/or qualitative)	Inexpensive. Widely available Very good NPV	PPV dependent upon background Hp prevalence. Not recommended after Hp therapy
B) Urea breath tests (^{13}C and/or ^{14}C)	Identifies active Hp infection. Excellent PPV and NPV regardless of Hp prevalence. Useful before and after Hp therapy	Reimbursement and availability remain inconsistent
C) Fecal antigen test	Identifies active Hp infection. Excellent NPV and PPV, regardless of Hp prevalence. Useful before and after Hp therapy	Polyclonal test less well validated compared to the UBT in posttreatment settings. Monoclonal test appears reliable before and after Hp therapy.

The sensitivity of all tests (endoscopic and nonendoscopic) that identify active Hpi infection is reduced by the recent use of PPIs, bismuth, or antibiotics
PPI = proton pump inhibitor; NPV = negative predictive value; PPV = positive predictive value; UBT = urea breath test.

Table 2: Possible reasons for Helicobacter pylori treatment failure.

1	resistance acquired by mutations
2	the low gastric pH limits antibiotic efficacy
3	antibiotic concentration can be insufficient if there is a high bacterial load
4	existence of sanctuaries to which antibiotics do not diffuse
5	existence of viable bacteria in dormant forms not accessible to antibiotics
6	impaired host mucosal immunity
7	risk of re-infection
8	lack of patient compliance (due to adverse effects or poor understanding of complex antibiotic regimen)

TREATMENT

Historically, various combinations of antibiotics have been used to eradicate the infection, however, no optimal treatment has yet been defined, as there is not a single drug regimen that can eradicate it. There are many factors that have increasingly compromised the effectiveness of most commonly used therapies (as seen in table 2)[1].

These factors have reduced the eradication rates to unacceptable levels (< 80% in some geographic areas). As a response, new treatment strategies have been studied and recently been validated to replace the standard ones[15].

Eradication therapies should be guided ideally by individual susceptibility testing. As this is not cost-effective, local antibiotic resistance patterns should dictate the regimen. Another factor that influences the treatment strategy is drug availability in different countries[16]. These regimens can be divided into first-line treatment and second-line or rescue treatment and are summarized in table 3[1].

Table 3: Treatment regimens for Helicobacter pylori infection

First-line therapies		
Regimen name	*General characteristics*	*Duration*
“Standard triple treatment”	simultaneous PPI + clarithromycin + amoxicillin (each twice daily)	7 days
10 or 14 days triple	simultaneous PPI + clarithromycin + amoxicillin (each twice daily)	10 or 14 days
Sequential therapy	5 or 7 days simultaneous PPI + amoxicillin, followed by 5 or 7 days simultaneous PPI + clarithromycin + 5-nitroimidazole (each twice daily)	10 or 14 days
Quadruple therapy	Simultaneous PPI (twice daily) + bismuth subsalicylate, metronidazole and tetracycline (each 4 times daily)	10 or 14 days
Second-line and rescue therapies		
Regimen name	*General characteristics*	*Duration*
Concomitant therapy	Simultaneous PPI + 3 antibiotics (often amoxicillin, clarithromycin, and 5-nitroimidazole) (each twice daily)	7, 10 or 14 days
Levofloxacin therapies	Levofloxacin will replace clarithromycin in triple, sequential or concomitant regimens	7, 10, 14 days
Hybrid therapy	7 days simultaneous PPI + amoxicillin, followed by 7 days simultaneous PPI + amoxicillin + clarithromycin + 5-nitroimidazole (each twice daily)	14 days
Rifabutin triple therapy	PPI + amoxicillin + rifabutin (each twice daily)	14 days

PPIs are mandatory compounds in every regimen and are administered twice daily at standard doses: omeprazole 20 mg, esomeprazole 40 mg, lansoprazole 30 mg or pantoprazole 40 mg (with studies showing higher eradication rates for the more potent second-generation PPIs – namely esomeprazole). Standard antibiotic dosages are used in all treatment regimens: amoxicillin 1 g, clarithromycin 500 mg, metronidazole 500 mg, tinidazole 500 mg, bismuth subsalicylate 524 mg or bismuth subcitrate 420 mg, tetracycline 500 mg, levofloxacin 500 mg, and rifabutin 300 mg[17].

A recently published meta-analysis by Li et al. has compared many of the available regimens for efficacy and tolerance. In terms of efficacy, the standard triple therapy was outranked by all other regimens, with the best eradication rates for the sequential therapy amongst first-line treatments and for the concomitant therapy amongst rescue treatments. The same study has shown that increased treatment duration improves eradication rates, but at the same time enhances the likelihood of adverse effects, lowering patient compliance – almost all rescue regimens were poorly ranked in terms of tolerance[18]. Because of the fact that none of these regimens is ideal, eradication should always be assessed, preferably using a non-invasive test (eg: urea breath test or stool antigen test). Confirmation of eradication can also provide an early image on the pattern of antibiotic resistance in a specific population[15].

All this effort in treating Hp infection is justified by the many benefits of eradication for patience with PUD, but also some malignant conditions. For example a cured individual has better ulcer remission rates for both gastric and duodenal ulcer and does not need maintenance acid suppression therapy after eradication and ulcer healing[10]. It is also more cost-effective and superior compared to maintenance acid suppressive therapy in preventing duodenal ulcer[1]. As for malignant pathologies, early stage low-grade MALT lymphoma can be cured by Hp eradication up to 80% of cases and there is also the possibility of regression or decrease in progression of precancerous gastric lesions (atrophic gastritis and intestinal metaplasia) after eradication[15].

Other studies have shown inverse associations between Hp infection and the prevalence of certain diseases. A recent study published by Rubenstein et al. confirmed prior studies that showed a strong negative association between Hp infection (particularly the cagA strain) and erosive esophagitis, Barrett's esophagus or adenocarcinoma of the esophagus. However, contrary to the prevalent hypothesis explaining this association, they were unable to detect a negative association between Hp infection and gastroesophageal reflux disease symptoms[19]. Lebwohl et al. found a strong inverse relationship between Hp presence and celiac disease (CD), but failed to establish the mechanism by which Hp might be protective against CD[20]. Other studies have postulated that Hp is protective against some extradigestive conditions, especialy asthma and other allergic pathologies in children[21].

THE ROLE OF PROBIOTICS IN HP MANAGEMENT

Probiotics are defined by the World Health Organization (WHO) as "live microorganisms which, when administered in adequate amounts, confer a health benefit on the host". Most commonly used in clinical practice are lactic-acid-producing micro-organisms (Lactobacillus spp. or Bifidobacterium spp.). Lactic acid produced by these probiotics can have a direct antimicrobial effect by lowering the pH, but can also inhibit the Hp urease. There is also increasing evidence in animal models that some strains of probiotics can inhibit H. pylori growth by competing with different adhesion sites in the gastric mucosae. Another mechanism being stipulated is that some probiotics can increase the expression of the MUC2 and MUC3 genes, which can subsequently lead to an increase of mucus thickness in both antrum and corpus after long-term probiotic intake.

Many studies have been conducted in this field and by analyzing some of them Enzo et al. have reached the conclusion that the use of probiotics as an adjuvant to PPI–antibiotic treatment could improve eradication rates, but the main benefit of this association is the prevention of side-effects, leading to better patient compliance[22].

FUTURE THERAPIES

Efforts to develop a vaccine against H. pylori began in early 1990`s with initial attempts to promote a localized mucosal immune response in the stomach via oral vaccines. Recently, an intramuscularly trivalent vaccine (recombinant Cag-A, Vac-A, and neutrophil-activating protein) was developed, but failed to induce immunity, despite the fact that these antigens were recognized by the host’s humoral and cellular immune systems. Although considerable progress has been made in understanding the innate and adaptive immune response against Hp infection, it is still uncertain how to promote the development of host immunity with the final goal of creating a successful vaccine[23].

DISCUSSIONS AND CONCLUSIONS

Despite the constant progress made in the management of Helicobacter pylori infection, it is still considered a major public health issue due to it`s high prevalence (especially in developing countries) and various conditions that can arise from it (even though 80-85% of infected individuals are asymptomatic). The main reasons for treatment failure is resistance acquired by mutations and lack of patient compliance and recent studies are showing that the standard triple therapy is out-performed in effectiveness by most other treatments. Probiotic adjuvant therapy appears to have a clear effect in reducing side effects, but insufficient data exists to conclude that their use improves eradication rates. Knowing that there is no “gold-standard” in Hp eradication therapy and falling short of the individual susceptibility testing goal, the regimen should be dictated by local antibiotic resistance patterns.

SYSTEMATIC REVIEW

Current therapeutic strategies for erectile function recovery after radical prostatectomy – literature review and meta-analysis

Cătălin Belinski[1], Alexandru Aungurenci[1], Dragoș Marcu[2], Dan Spînu[2], Ovidiu Bratu[2,3], Dan Mischianu[2,3]

INTRODUCTION

Radical prostatectomy is the most commonly performed treatment option for localised prostate cancer. In the last decades the surgical technique has been improved and modified in order to satisfy both oncological safety and postoperative functional results. Urinary incontinence and erectile dysfunction (ED) are the main postoperative functional impairments in patients that undergo radical prostatectomy (RP). [1]

According to the EAU Guidelines erectile dysfunction is defined as "the persistent inability to attain and maintain an erection sufficient to permit satisfactory sexual performance". To this moment it is estimated that 25-75% of the patients who underwent RP develop ED with major implications in postoperative quality of life. [2] Various risk factors can be related to post-prostatectomy ED, among which the most important are the patient's age, comorbidities, preoperative erectile function, but also surgical approach (robot-assisted, laparoscopic, open) and nerve-sparing technique (inter/intrafascial). [2, 3] Among physiopathological modifications that concur to ED, the nerve damage (neuropraxia) appears to be the main domino piece that triggers other alterations like structural changes of the smooth muscle, arterial damage and veno-oclusive dysfunction which lead to cavernosal oxygenation impairments. [4–6] The clinical results of physiopathological alterations are shortening of penile size, impairment of orgasm and ejaculation achievement which have tremendous impact on psychological and mental health. [5]

Various treatment options include oral medication with phosphodiesterase 5 inhibitors (PDE5i), intracavernosal injections or intraurethral applications of prostaglandin E1 (PGE1), vacuum or vibratory treatments. Though there are many options for ED treatment, to this date there is no definitive protocol for penile rehabilitation (PR) after prostatectomy. [5, 7] In this regard we have made a literature review and meta-analysis of the most important randomised trials published in the last 5 years in order to find the best strategies of penile rehabilitation after radical prostatectomy.

MATERIALS AND METHODS

We have systematically reviewed and collected data from randomised trials published in the last 5 years involving patients diagnosed with prostate cancer who experienced ED after radical prostatectomy. In order to find the necessary trials we have searched PubMed and ScienceDirect databases and used several key words like: erectile dysfunction, penile rehabilitation, phosphodiesterase 5 inhibitors, erectile functional recovery, prostate cancer, prostatectomy and nerve sparing – in various combinations. The first aspect for our meta-analysis inclusion criteria was to identify randomized (prospective or retrospective) placebo-controlled trials involving patients with localised prostate cancer that benefited of nerve sparing radical prostatectomy and developed postoperative ED. The key aspect of our research was the penile rehabilitation strategy which included the therapeutic means used for erectile

[2] Dr. Carol Davila University Central Emergency Military Hospital, Bucharest, Romania
[3] Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

function recovery and the treatment duration. Other aspects followed by us regarded the means of ED assessment, the surgical means and invasiveness and the rate of treatment success reported to ED severity.

In this regard we have conducted our research for each year between January 2014 and December 2018 and reviewed a total of 631 articles published on this theme collected from both search engines. For a time-efficient assessment we have read the title and abstract of each article and included only those articles that matched our criteria. We have excluded the reviews and meta-analyses and also the trials of ED that was not related to prostate cancer surgery. That left us 194 publications from which to select. We have also excluded the trials withdrawn from database for various reasons and articles that didn't followed the therapeutic means of ED recovery. Finally we have selected 15 articles matching our criteria for meta-analysis that were thoroughly full text reviewed. Seven out of the 15 were prospective randomised trials, 2 of them being double-blind, placebo-controlled. Another 2 were nonrandomised prospective trials and the rest of 6 articles were retrospective review. Although some studies included by us followed-up both the ED and postoperative incontinence problem, we have concerned strictly on erectile dysfunction issue and collected the necessary data.

For statistical analysis we have used ReviewManager 5.3 and Microsoft Excel software with data of treatment strategies and drug dosages collected from the studies. Although there was less heterogeneity between the study designs of the included articles we found important data about postoperative EF recovery. These data allowed us to include the studies in subgroups in order to analyse them.

Table 1. Distribution of included studies

Trial author	Design	Patient no.	Mean age	Cardiovascular comorbidities	Diabetes

Sooriakumaran et al. [19]	Prospective non-randomised	2545	63.3	556 (35.2%)	99 (6.2%)

RESULTS

A total of 11,831 patients were enlisted in the 15 studies we have included for analysis. Mean age of all patients was 61.91 years with a range between 54 and 67.9 years. (Table 1) Although not all the studies specifically mentioned the most encountered comorbidity was the cardiovascular disease (37.5% - 100%) followed by diabetes mellitus (6.2% – 16.07%). For most ED patients the presence of cardiovascular comorbidities creates the premises of disease trigger, followed by diabetes and obesity. [] All patients were diagnosed (by means of PSA, prostate biopsy and pelvic MRI) with localised prostate cancer mainly T1c - T2c, with Gleason score ranging between 6 and 7 and PSA values below 10 ng/ml. (Table 2) These data were correlated with the postoperative pathology findings which in some cases changed the actual diagnostic stage according to d'Amico criteria. As it can be seen in Table 2 in some cases based on the degree of invasion the cancer stage was changed from localised to locally-advanced (T3b-T4) and based on Gleason score from low or intermediate risk to high risk (Gleason 8).

All patients were proposed for radical prostatectomy using various approaches: open surgery (n = 4,460), conventional laparoscopy (n = 1,371) or robot assisted laparoscopic prostatectomy (n = 4,929). (Table 2) Most patients benefited of bilateral nerve sparing (BNS) dissection of the nerve bundles (n = 6,852) by al known technical procedures (interfascial/intrafascial), which represented 63.68% of the operated patients. When case did not impose BNS dissection, unilateral nerve sparing technique was attempted (n = 3,209) which was performed in 29.82% of the operated patients. The rest of 6.5% of the patients either had not benefited of NS dissection either the information about the NS status was not mentioned. [16, 18, 19] The NS status at the end of the surgery was crucial because it ensured the premises for postoperative ED recovery although most of the patients experienced postoperative neuropraxia.

Table 2. PCa status and surgical approach for each study

Trial author	PCa clinical stage	Gleason Score	Surgical approach			Nerve sparing	
			OP	CLP	RALP	BNS	UNS

PPP – preoperative potent patients; IIEF – International Index of Erectile Function; OaD – oance a day; PRN – pro re nata (on demand); ICI – intracavernosal injections; IUr – intrauretral;

For pre and postoperative EF assessment the IIEF questionnaire was preferred in most of the studies in different forms: the classical 15 questions IIEF-EF or the shorter IIEF-5/IIEF-6 questionnaires.

Most authors preferred the IIEF-5 questionnaire due to its reliability and rapid way of determining the EF status. (Table 3) In most of the studies that used the IIEF questionnaire a cut-of value of 22 points was established for preoperative potent men [8–10, 13, 14] while others established close cut-of values. [16, 20] Only two studies used other means of EF assessment. Sooriakumaran et al. used two questions about penile stiffness and morning erections, both having single choice answer from 5 possible variants. [19] In a particular case Kim et al. compared the penile length both pre and postoperative and additionally used the SHIM questionnaire for ED appraisal. [20]

The most frequently used treatment method for penile recovery was the administration of PDE5i which was tested with various ways of administration and dosages and compared with placebo or no treatment control groups. The most commonly used drug in the included trials was Tadalafil [9, 10, 13, 14, 20], followed by Sildenafil [17, 22] and Vardenafil. [11] Some trials studied the single use treatment of PDE5i compared with combinations of PDE5 with PGE1 ICI [8, 15, 18] or penile vibratory stimulation (PVS) devices. [12] There were also particular studies that did not compare the method of PDE5i administration but rather the rate of EF recovery [8, 21], the moment of treatment initiation [22] or the length of treatment administration. [18] Haglid et al. compared the EF recovery based only on the surgical approach type (open vs. RALP) and not interfering with any medication in this regard while Sooriakumaran et al. compared the same surgical approaches using PGE1 treatment setting. [16]

Figure 1: Multivariate comparison of PDE5i OaD and PRN treatment compared to control group

	PDE5i OaD			Control				Std. Mean Difference

Although the articles included in our meta-analysis had dichotomous criteria of study design we could find similarities between some of them, which allowed us to organise subgroups of trials. On multivariate analysis we have included trials in which PDE5i was administered as OaD and PRN treatment compared to a pacebo control group. The variables included in analysis were the mean IIEF scores recorded at the end of the trial for each group (OaD, PRN and control). As it can be observed in fig. 1 the higher rates of recovery are in favour of PDE5i OaD group compared to control group (CI 95%, P < 0.0001). On a lower scale, the same result could be observed when PDE5i OaD treatment was compared to PDE5i PRN although in this analysis only 2 studies had the necessary data to be included (CI 95%, P =

0.48).

In a univariate analysis we also compared the trials were only the percentage of recovered patients after PDE5i treatment was given. (Fig 2) As in previous assessment the PDE5i OaD group had higher recovery rates compared to control group (CI 95% P = 0.40). Also when we have compared PDE5i OaD with PRN group the better results were slightly higher in favour of OaD group thus resulting that the benefit of PDE5i OaD compared to PRN treatment was minor (CI 95%, P = 0.95).

Figure 2: Recovery rates in trials using PDE5i OaD and PRN treatment compared to control group

DISCUSSION

Erectile dysfunction is a major postoperative complication for men who undergo radical prostatectomy, alongside urinary incontinence. At this moment prostate cancer is the second most diagnosed neoplasia in men due to the systematic determination of PSA. [23] Radical prostatectomy remains the most important therapeutic procedure for localised PCa having a postoperative life-expectancy of 10 years. [2] Although the technical enhancements of prostatectomy reduced the rates of postoperative complication, ED still remains one of the most complex problem for PCa patient's quality of life.

Even if the nerve sparing dissection technique of the prostate bundles partially improved the ED rates, there are still problems regarding the postoperative penile rehabilitation. Neuropraxia is the main pathological alteration that leads to major structural changes of the penile tissue. This can also lead to veno-oclusive dysfunctions of blood drainage. Due to the constant state of hypo-oxygenation the penile smooth muscles suffers a process of apoptosis and fibrosis which in time are producing irreversible penile malformations such as penile shortening of 2-3 cm and Peyronie disease. [5, 24] In this regard it is advisable that urologists should discuss with their patients about the possibility of postoperative ED in various rates – from temporary to permanent. [25]

Two trials included in our meta-analysis studied the rate of ED occurrence and penile recovery degree after RALP compared to RRP in high volume centres from Sweden. In a 2015 prospective study, Haglid et al. found a slightly higher rate of penile recovery for RALP, but the differences were not significant for these two surgical approaches. [16] In a recently conducted prospective trial, Sooriakumaran et al. (2018) found earlier recovery rates of EF for RALP (21%) compared to RRP (14%) due to a more precise identification and preservation of nerve bundles during RALP. Also the rates of post-surgical positive margins were similar to open surgery which is an important aspect for oncological radicality. [19] Both studies were prospective non-randomised.

One key aspect of ED diagnosis is the use of pre and postoperative EF assessment questionnaires. As we have shown above the most frequently used questionnaire was IIEF-5 which is the short version of the IIEF-EF questionnaire. Other questionnaires like Sexual Health Inventory for Men (SHIM) or Expanded Prostate Cancer Index Composite (EHGS) have similar predictive results to IIEF and should be routinely used for postoperative ED diagnosis. [25, 26]

It is a known fact that older age, cardiovascular comorbidities and diabetes mellitus are the most important predictive factors for ED onset. [27, 28] On the other hand the younger age and the lower body mass index are demonstrated protective factors for ED recovery. [2] Even though not all the studies included in our meta-analysis reported the rate of cardiovascular disease and diabetes mellitus we could emphasize that in the post prostatectomy setting these two comorbidities could have significant impact on ED onset and the subsequent penile recovery. [10, 14, 15, 19, 20, 21]

Penile rehabilitation is the cumulus of therapeutically means which includes medication, medical devices or actions, simple or in various combination recommended for erectile function recovery. [5] PDE5i are the most frequently used drugs in clinical practice for penile rehabilitation and to this date is the most studied therapeutic method administered to ED patients. The main advantage of PDE5i therapy is that there are quick and easy to administer but it requires the integrity of at least 1 cavernosal nerve bundle. Also the treatment cost and side effects (headache, flushing and palpitations) are not negletable. [24]

In their common trial Montorsi et al. (2014) and Stolzenburg et al. (2015) studied the effect of Tadalafil administered once a day (OaD) and on demand (PRN) compared to a placebo-controlled group and found that the OaD administration of Tadalafil 5 mg has the best results for penile recovery after prostatectomy. [9, 13] Similar results for Tadalafil OaD administration were also found by Seo et al. (2014), Canat et al. (2015) and Kim S. et al. (2018) based on the mean IIEF score at the end of the trial. [14, 20] Nakano et al. (2014) and Kim D. et al. (2016) found similar results at the end of their trials although they have studied the effect of Vardenafil respectively Sildenafil. [11, 17] In our multivariate analysis the PDE5i OaD treatment has evident advantages over placebo and on demand PDE5i administration for postoperative penile recovery rate.

Regarding the choice of PDE5i treatment there are no specific trials that compare the efficiency of currently available substances in postoperative ED. In a 2005 open-label randomised trial Eardley et al. emphasized that Tadalafil is the preferred PDE5i used for ED treatment because of long-lasting effect in time compared to Sildenafil that allowed patients to have less concerns about spontaneity of erection. [29] Further more Hyndman et al. demonstrated in their randomised trial that Sildenafil could have major impact over urinary continence, thus impairing the overall recovery of PCa operated patients. [30]

Prostaglandin E1 intracavernosal injection (PGE1 ICI) was the first type of treatment for postoperative EF recovery, introduced and studied by Prof. Montorsi et al. [31] The most important advantage of PGE1 ICI is that is very effective in any type of surgical approach even if nerve sparing was not indicated, though the cost, the need to refrigerate the product, the invasiveness of the treatment and the side effects are a majos counterbalance for treatment initiation. [24] In our meta-analysis, Vickers et al., Yiou et al. and Capogrosso et al. have used PGE1 ICI in combination with PDE5i treatment for penile recovery. The results achieved by Yiou at 12 respectively 24 months of combined treatment were very similar in both drug-administered and control group. [15] On the other hand Capogrosso et al. found that at 24 months of combined PGE1 ICI and PDE5i treatment the rates of recovery were higher than at 12 months (34% vs. 27%). [18]

Vacuum and vibratory devices are non-invasive and very effective in EF recovery especially when combined with PDE5i treatment. Fode et al. demonstrated in their randomised prospective trial that EF recovery could be very effective when penile vibratory stimulation devices are used in conjunction with PDE5i (53% recovery rate) compared to PDE5i only group (32%). [12]

Regarding treatment initiation Jo et al. demonstrated that early penile rehabilitation commencement (at 3 weeks after surgery – immediately after urinary catheter removal) has better recovery results than delayed treatment initiation (at 3 months postoperative). [22]

CONCLUSIONS

The postoperative EF recovery of PCa patients can be achieved using a multitude of penile recovery strategies. For this purpose a preoperative assessment is very important, by using erectile function questionnaires. Patients should be informed about the postoperative ED risk and should be counselled in this area.

Nerve-sparing robot assisted laparoscopic prostatectomy is the most protective surgical approach for EF preservation. PDE5i is the main therapeutic approach for postoperative penile recovery.

Tadalafil 5 mg once a day was the most effective long term therapy for ED treatment both single use or in combination with PGE1 and other devices (vacuum or vibratory stimulation). Penile prosthesis implants should be regarded as last resort treatment option for cases when no penile recovery strategy has been successful.

REVIEW ARTICLE

Current treatment of posttraumatic stress disorder – A review of therapeutic guidelines and good practice recommendations

Octavian Vasiliu, Daniel Vasile, Andrei G. Mangalagiu, Bogdan M. Petrescu, Cristian A. Candea, Corina Tudor, Daniela Ungureanu, Madalina Miclos, Alina Draghici, Catalina Florescu, Roxana E. Bratu-Bazic

Abstract: *A unique approach to the treatment of posttraumatic stress disorder (PTSD) is difficult to support, because of the complexity and heterogeneity of this pathology. Multiple evidence-based guidelines for PTSD treatment exist, elaborated by prestigious institutions around the world, but a certain level of the inconsistency of their recommendations appears when these sources are compared with each other. Therefore, a review of current guidelines and extraction of the most supported by evidence recommendations is considered important for clinical practice, due to the need to approach such complex cases as PTSD-diagnosed patients in a stepwise manner. Structured monitoring of the clinical status during the treatment is also an important and rather neglected aspect of the case management in PTSD, and the necessity of follow-up visits for efficacy and tolerability should be taken into consideration. Psychotherapy (especially cognitive-behavioral oriented therapies and eye movement desensitization and reprocessing therapy) is supported by evidence as a first-line approach, as well as certain antidepressants, like the selective serotonin reuptake inhibitors and venlafaxine. Many second-line pharmacological agents and psychotherapies are also available, but there is an obvious need for more pragmatic trials with PTSD patients.*

Keywords: *post-traumatic stress disorder, psychotherapy, case management, antidepressants, therapeutic guidelines, good clinical practice*

BACKGROUND

While definitions of the diagnostic criteria for posttraumatic stress disorder (PTSD) are articulate and comprehensive in both the World Health Organization and American Psychiatric Association classifications of mental disorders [1-3], pragmatic recommendations for the treatment of this disorder are still lacking. Although there are several guidelines dedicated to this subject, they are based on randomized trials, and not on pragmatic, naturalistic studies, which leave some important questions unanswered. Even if the case management is based on these guidelines, there are several contradictions based on the different data they included. Therefore, we consider the first necessary step to be a critical analysis of these therapeutic guidelines, followed by the formulation of good practices and hierarchized recommendations, according to the GRADE level [4].

The diagnosis of PTSD could be formulated, according to ICD-11, if an extremely threatening or horrific event or series of events is followed by re-experiencing this trauma as intrusive memories, flashbacks, nightmares, accompanied

„Dr. Carol Davila” Central Military Emergency University Hospital, Bucharest, Romania

by strong or overwhelming emotions and strong physical sensations; avoidance of thoughts and memories of the event(s), or avoidance of activities, situations, or people reminiscent of the events(s); persistent perceptions of heightened current threat, for example, indicated by hypervigilance or an enhanced startle reaction to stimuli such as unexpected noises [1]. These symptoms have to persist for at least several weeks and to cause significant impairment in personal, family, social, educational, occupational, or other important areas of functioning to support a PTSD diagnosis [1]. The ICD-10 mentions the capacity of the stressful event to cause pervasive distress in almost anyone who has been removed from the latest edition of this classification [1,3]. Also, differences in the structure of the symptoms list necessary to establish the PTSD criteria have been formulated between the two editions of ICD, from 13 in the tenth edition, to only 6, by removing the non-specific manifestations [1,3]. In the latest edition of the American Psychiatric Association classification of mental disorders (2013), there are 4 clusters of symptoms needed for the diagnosis: (1) intrusion symptoms associated with the traumatic event, (2) persistent avoidance of stimuli associated with the traumatic event, (3) negative alterations in cognitions and mood associated with the traumatic event, (4) marked alterations in arousal and reactivity associated with the traumatic event, and the duration of these manifestations are more than one month [2].

Complex PTSD may develop following exposure to an event or series of events of an extremely threatening or horrific nature, commonly prolonged or repetitive events from which escape is difficult or impossible [1]. Complex PTSD is characterized by severe and persistent problems in affect regulation, beliefs about oneself as diminished, defeated, or worthless, accompanied by feelings of shame, guilt, or failure related to the traumatic event; difficulties in sustaining relationships, and feeling close to others [1]. These symptoms cause significant impairment in personal, family, social, educational, occupational, or other important areas of functioning [1].

A high rate of comorbid major depressive disorder (up to 50%) has been reported in PTSD patients, a phenomenon which underlines the necessity for a thorough psychiatric evaluation, both initially and during the monitoring period [5,6]. Also, there has been described as an overlap between PTSD and psychosis that may raise important diagnosis challenges and treatment dilemmas [7, 8]. Substance-related disorders have also been described with relatively high incidence in this population, and specific psychotherapy algorithms have been developed for these patients with dual diagnosis, based on imaginal and in vivo exposure for PTSD, applied concomitantly with cognitive-behavioral techniques for substance use disorders [9]. Also, the pharmacological treatment should be adjusted according to the existing comorbidities, and the case manager should integrate all the data, taking into account the risk of pharmacologic interactions, contraindications, and side effects (e.g., avoidance of drugs with the risk of addiction, like benzodiazepines, is recommended in PTSD patients) [10].

ANALYSIS OF THE CURRENT THERAPEUTIC GUIDELINES FOR PTSD

Several prestigious institutions have elaborated evidence-based guidelines for the treatment of PTSD, therefore an important number of recommendations for approaching these patients to exist. While some therapeutic guidelines are focused on psychotherapy, others are based on pharmacological research, while still others encompass both types of treatment.

American Psychological Association Clinical Practice Guideline for the Treatment of PTSD (2017) strongly recommends as evidence-based psychotherapies in adults cognitive-behavioral therapy (CBT), cognitive processing therapy (CPT), cognitive therapy (CT), and prolonged exposure therapy (PE), and suggests the use of brief eclectic psychotherapy (BEP), eye movement desensitization and reprocessing therapy (EMDR), and narrative exposure therapy (NET) [11].

According to the **Australian Guidelines for the Treatment of Acute Stress Disorder and Posttraumatic Stress Disorder** (2013), individual-trauma focused CBT, including exposure and/or cognitive therapy, should be recommended if symptoms are consistent with acute stress disorder or posttraumatic stress disorder in the initial 4 weeks after a potentially traumatic event (level C evidence) [12]. Individuals with posttraumatic stress disorder benefit from trauma-focused CBT or EMDR (level A recommendation), and if the symptoms did not respond to these interventions, non-trauma focused approaches may be considered (e.g., stress inoculation technique) [12]. Also, there is some evidence that supports the efficacy of in vivo exposure therefore, by expert consensus, it is recommended to include this method in the treatment [12]. Group CBT (trauma-focused or non-trauma focused) may be offered as an adjunctive to trauma-focused individual therapy [12].

Medication should not be used for the treatment of acute stress reaction or posttraumatic stress disorder within the four weeks of symptom onset unless the severity of such symptoms- associated distress cannot be managed by psychological means alone [12]. The pharmacological approach may be continued while people are undertaking psychological treatments, but several agents, like benzodiazepines, may interfere with some effective psychological treatments [12]. SSRIs are considered the first line for the treatment of posttraumatic stress disorder [12].

According to the **Maudsley Prescribing Guidelines** (13th edition, 2018) patients diagnosed with posttraumatic stress disorder should be offered as the first line of treatment paroxetine, sertraline, fluoxetine (up to the maximum tolerated doses) or venlafaxine (37.5-300 mg/day) [13]. As second-line treatment the case manager could choose between antipsychotics (olanzapine 5-20 mg/day, risperidone 0.5-6 mg/day, quetiapine 50-800 mg/day), mirtazapine 15-45 mg/day, monoaminoxidase (MAO) inhibitors (phenelzine 15-75 mg/day), tricyclic antidepressants (amitriptyline 50-300 mg/day, imipramine 50-300 mg/day), and prazosin (2-15 mg nocte) for nightmare and sleep disturbances [13]. Possible choices if the first and second lines failed are duloxetine (60-120 mg/day), lamotrigine (up to 500 mg/day), phenytoin, valproate, or i.v. ketamine, and as non-drug therapies- eye-movement desensitization and reprocessing (EMDR) and trauma-focused CBT [13].

According to the **VA/DOD Clinical Practice Guideline for the Management of PTSD and ASD** (2017) pharmacotherapy in PTSD is classified as follows: sertraline, paroxetine, fluoxetine, venlafaxine as monotherapy (moderate evidence), nefazodone (low evidence), imipramine, phenelzine (very low evidence) [14]. The Work Group recommended against the use of atypical antipsychotics, benzodiazepines, and Divalproex as augmentation therapy due to low-quality evidence and potential adverse effects [14]. Also, prazosin is not supported by this guideline for the use in monotherapy or combination with other agents [14]. Individual trauma-focused psychotherapy for PTSD are Prolonged Exposure, Cognitive Processing Therapy, and EMDR, which are supported by the strongest evidence, but other therapies like specific cognitive therapies for PTSD, Brief Eclectic Psychotherapy, Narrative Exposure Therapy, written narrative exposure may be recommended [14]. If individual trauma-focused psychotherapy is not available, Stress Inoculation Therapy, Interpersonal Therapy, or Present-Centered Therapy may be recommended [14].

The **International Society for Traumatic Stress Studies new guidelines for the Prevention and Treatment of Posttraumatic Stress Disorder** (2019) has formulated the following recommendations according to their evidence-based status: (1) strong support for cognitive processing therapy, cognitive therapy, EMDR, individual CBT with a trauma focus, prolonged exposure; (2) standard recommendations for CBT without a trauma focus, guided Internet-based CBT with a trauma focus, narrative exposure therapy, present-centered therapy; (3) emerging evidence- couples CBT with a trauma focus, group and individual CBT with a trauma focus, reconsolidation of traumatic memories, single-session CBT, written exposure therapy, and virtual reality therapy [15].

Individual trauma-focused CBT intervention may be useful for adults who have acute stress disorder or clinically important symptoms of PTSD and have been exposed to 1 or more traumatic events within the last month- cognitive processing therapy, cognitive therapy, narrative exposure therapy, prolonged exposure therapy, according to the **NICE Guidelines** (2018) [16]. In adults with PTSD symptoms should be offered trauma-focused CBT, during 8-12 sessions, accompanied by psychoeducation about reactions to trauma, strategies for managing arousal and flashbacks, safety planning, or EMDR for patients with PTSD symptoms, if the patient has a preference for this method [16]. Trauma-focused computerized CBT for adults with a diagnosis of PTSD or clinically important symptoms of PTSD more than 3 months after a traumatic event, who do not want to be engaged in trauma-focused CBT or EMDR [16]. Symptom-specific CBT interventions for adults with a diagnosis of PTSD or clinically important symptoms of PTSD more than 3 months after traumatic events who are unable or unwilling to engage in a trauma-focused intervention that targets PTSD or have residual symptoms after a trauma-focused intervention [16].

Medication should not include benzodiazepines for the prevention of PTSD in adults, but venlafaxine or an SSRI may be chosen [16]. Antipsychotics may be offered if patients have disabling symptoms (psychotic) or if their symptoms have not responded to other drug or psychological treatments [16].

For patients with complex PTSD the case manager should help the patient control any symptoms (e.g. dissociation or emotional dysfunctions) that might interfere with engaging in trauma-focused therapies; ensure adequate time for the construction of the therapeutic relationship; to increase the number of trauma-focused therapy sessions according to the person’s needs; plan any ongoing support the person needs and has implications in the therapeutic management [16].

DESCRIPTION OF THE MAIN PSYCHOTHERAPEUTIC METHODS IN PTSD

Cognitive-behavioral therapy (CBT) in PTSD is focused on the relationship among thoughts, feelings, and behaviors that are present-oriented and target current problems and symptoms [17]. CBT is based on emotional processing theory and social cognitive theory, therefore it claims that changing associations between reminders of the traumatic event and responses will lead to healthier behaviors while reframing the relation between trauma and existing beliefs about self, others and the world will also help decrease self-blame and improve the processing of the trauma [17].

Cognitive distortions in PTSD include perceiving the world as dangerous, seeing him/herself as powerless, and feeling guilty about surviving while other significant ones have died [18]. Cognitive therapy fosters the development of more realistic and adaptive cognitions, by successful processing of the traumatic event, with engaging and organization of the trauma narrative [18, 19].

Cognitive processing therapy (CPT) is an efficient method for treating PTSD as demonstrated by a recent meta-analysis (n=11 studies, N=1130 participants), outperforming inactive control conditions on PTSD outcome measures at posttreatment and follow-up, but also other active treatments at posttreatment but not at follow-up [20]. Effect sizes of CPT were superior to 89% of the inactive control conditions at posttreatment and 82% at follow-up, which indicates a large and sustained effect of the CPT [20].

Veterans who were diagnosed with both PTSD and alcohol use disorder (AUD) completed a 6-week CPT-based program had significantly better outcomes, including trauma-related cognitive distortions, PTSD symptoms, depressive symptoms, and trauma-cued substance craving [21]. In another study that included veterans (n=465), enrolled in CPT plus a written trauma account either group format or individual, the PTSD and depressive symptoms decreased significantly, with medium effects for the first option, and large effects for the second treatment [22].

Cognitive therapy (CT) has proven efficient in a group of 20 patients diagnosed with PTSD, as it decreased core PTSD features, but also depressive and anxiety symptoms [23]. Good treatment outcomes were related to more changes in dysfunctional cognitions related to the trauma [23]. Intensive CT was applied in 14 patients diagnosed with PTSD, in an 18-hour format during 5-7 working days, followed by one session a week later and up to 3 follow-up sessions; intensive CT led to similar outcomes as weekly-administered CT, but the intensive treatment improved the key PTSD symptoms over a shorter period and led to greater reductions in depression [24].

Prolonged exposure therapy (PE) is another trauma-focused CBT effective for improving PTSD, with response rates in 60-65% of trauma victims suffering from this disorder [25]. PE is based on two types of exposure techniques, imaginal exposure, and in vivo exposure, and it is used for enhancing emotional processing through systematic confrontation with trauma-related stimuli [26-28]. Intensive PE therapy (12 sessions, 90 minutes each, during 4 days) followed by four weekly 90-minute booster PE sessions in an open trial (n=73) patients diagnosed with PTSD who presented multiple interpersonal trauma had positive results after repeated treatment attempts [29]. Exposure therapy has an impact on the fear and contextualization circuits by facilitating communication between the ventromedial prefrontal cortex, hippocampus, and the amygdala [30].

Brief eclectic psychotherapy (BEP) for PTSD is a manualized technique that combines elements from psychodynamic, cognitive-behavioral, and directive psychotherapy [31]. Psychoeducation with the participation of the spouse, and exposure used to help the patient to access his or her feelings related to the traumatic event are also used during BEP [31]. A 16-session protocol of BEP in PTSD includes the following steps: psychoeducation for the development of self-control and motivation for therapy (the patient is invited to call up his memories and related emotions one last time); imaginal exposure or guidance (brief periods of muscle relaxation, relieving of the traumatic experience by imaginal exposure of 20-30 minutes); writing tasks and mementos (for uncovering the difficult feelings that may be related to the traumatic experience); meaning and integration (exploring and accepting a new view of the world and the self); farewell ritual (symbolic ritual created to encourage the expression of the sorrow the patient may still feel, and then to leave behind these feelings) [31, 32].

The first randomized clinical trial for BEP in patients with PTSD included 42 police officers who received 16 weekly sessions (60 minutes each) of psychotherapy [32]. At posttest and follow-up (at 3 months) BEP had produced significant improvement in PTSD symptoms, work functioning, and several comorbid conditions (e.g., agoraphobia) [32].

Another clinical trial included patients diagnosed with PTSD (n=24) randomly assigned to BEP or a waitlist group for 4 months, with superior efficacy on PTSD core symptoms and general anxiety symptoms in the active intervention group [33]. In this trial, BEP consisted of 16 weekly sessions (45-60 minutes each), and a high rate of the dropout was recorded (25% for the treatment group) [33].

Eye movement desensitization and reprocessing therapy (EMDR) is a type of psychotherapy developed by F.Shapiro for intervention in emotional trauma and other negative life experiences [34]. This psychotherapy consists of a protocol with 8 phases and bilateral stimulation targeting patient desensitization from the discomfort induced by traumatic memories [35]. The final objective of the EMDR is to achieve the reprocessing of these memories and to integrate them within the autobiographical memory [35].

According to a review of 24 randomized controlled trials, EMDR is an evidence-based approach for this kind of disorder, with 7 out of 10 studies reporting EMDR to be faster acting and/or more effective than trauma-focused CBT [34]. Two meta-analyses supported the efficacy of EMDR in treating PTSD, with results superior to various interventions and control conditions, and showed the efficacy of this psychotherapy over symptoms of depression, anxiety, and subjective distress [36,37]. A review of the trials published between 2014 and 2017 regarding the efficacy of EMDR in PTSD further supported this method, because it improved core symptoms over time, compared to relaxation therapy and a waiting-list control group [38].

Narrative exposure therapy (NET) is a psychotherapeutic intervention dedicated to the treatment of survivors of multiple and severe traumas, and 3-6 sessions may be sufficient to provide significant relief [39]. It is a short-term approach based on CBT and testimony therapy [40]. NET was evaluated in a group of 59 political detainees, 18 of which had full PTSD criteria, who were allocated in a randomized manner to either one session of psychoeducation or five sessions of NET [41]. After 6 months, NET but not psychoeducation produced a significant reduction in PTSD symptoms and depression scores, although four out of the nine patients receiving NET and eight out of the nine patients undergoing psychoeducation still had PTSD symptoms at 6 months [41]. In another trial, NET was compared to supportive counseling and psychoeducation (4, 4 and one sessions, respectively) in a group of Sudanese refugees (n=43), and the results after one year of treatment were superior for NET (29% vs. 79% vs. 80% still had PTSD criteria) [40].

Interpersonal therapy (IPT) is a time-limited focused on the patient's actual events and reframing of the social functioning as a way to tackle the symptoms and may be recommended where the patient does not want to be exposed to exposure-based approaches [42]. In a case study, IPT proved itself efficient comparative to the other two psychotherapies, after 14 weekly sessions [42]. In a 14-week randomized trial, IPT was compared to prolonged exposure and relaxation therapy in 110 unmedicated patients with chronic PTSD and the response rates were 63% for IPT, 47% for prolonged exposure, and 38% for relaxation therapy, without significant differences between groups [43]. IPT and exposure therapy improved the quality of life and social functioning more than relaxation therapy [43].

Group Interpersonal Therapy (G-IPT) was evaluated in 13 patients diagnosed with chronic PTSD, in an 8-week treatment program, with favorable results [44]. The improvement was significant in social functioning, general wellbeing and depressive symptoms, and a moderate reduction in the avoidant symptom cluster of PTSD [44]. These positive effects were stable at 3 months and associated with perceived intra-therapy progress in solving problematic domains identified during IPT [44].

Present-Centered Therapy (PCT) for PTSD is a manualized psychotherapy originally designed as a treatment comparator in studies focused on the effectiveness of trauma-oriented CBT [45]. A systematic review of the randomized trials (n=12, N=1837 participants) states that moderate-quality evidence supports a superior efficacy of PCT in reducing PTSD severity compared to control conditions, and PCT was associated with lower drop-out rates comparative to trauma-focused CBT [45].

Stress inoculation training (SIT) is derived from CBT and proved itself efficient in veterans with PTSD [46]. According to this model, PTSD symptoms are maintained by an imbalance between perceived situational demands and perceived resources to fulfill the environmental and personal demands [47, 48]. The purpose of SIT is to increase the patient's feeling of self-confidence by helping him or her to control anxiety and related symptoms and to inoculate patients against possible future episodes of severe anxiety [48].

In a population with PTSD and traumatic brain injury (n=65 veterans), SIT was applied for 18 months in an outpatient clinic and the results supported the efficacy of this psychotherapy because significant reductions in PTSD and depressive symptoms were detected, as well as increases in perceived stress tolerance and performance in multiple life domains [46]. Improvements in social and occupational functioning were also reported [46].

In another trial, 96 female assault victims with chronic PTSD were randomized on prolonged exposure, SIT, combined prolonged exposure-SIT, or wait-list control [49]. All active treatments (9 twice-weekly individual sessions) decreased PTSD and depression symptoms compared to wait-list but did not differ significantly from each other, and these results persisted at follow-ups (3, 6, and 12 months) [49].

GOOD CLINICAL PRACTICE RECOMMENDATIONS

Therapeutic guidelines offer various and sometimes contradictory recommendations, therefore a critical analysis of the literature is granted to find common management strategies. While several guidelines are more cautious when recommending pharmacotherapy [12] and support a psychotherapeutic-based approach especially in the first stage of the PTSD, others are more focused on drug therapy [13], and still, others consider the type of approach should be selected according to the individual variables, including patient's preference, availability, etc [14].

We formulated GRADE recommendations according to 4 levels: A= high quality, defined as the level to what future research are very unlikely to change the validity of these recommendations; B= moderate quality, meaning that future research is likely to have an important impact on the appreciation of the recommendations; C=low quality, which means that it is very likely that future research will have an important impact over the confidence in the estimate of effect and is likely to change the recommendations; D= very low quality, defined by the uncertainty of any estimate of the effect [4].

A wide range of psychotherapies have been studied for patients with PTSD, but CBT and related techniques (CPT, CT, PE), as well as EMDR, are the most evidence-based approaches [11-15]. We consider a GRADE level A for these therapies is granted, based on the existing evidence. Level B evidence exists for BEP, NET, IPT, PCT, and SIT [31-33, 39-49].

The same level of evidence exists for SSRIs and venlafaxine, as these are the most supported by evidence pharmacological agents in PTSD patients [12-15]. If the first-line agents fail, then second-line agents may be used-mirtazapine, MAO inhibitors or tricyclics, or add-ons like atypical antipsychotics (level B of evidence) [13].

A structured diagnostic approach is strongly encouraged and adequate instruments should be used. Structured interviews (e.g., Mini-International Neuropsychiatric Interview, Composite International Diagnostic Interview, or Schedules for Clinical Assessment in Neuropsychiatry) are considered useful because of the high comorbidity rate met in PTSD patients [50-52]. Because the evolution of PTSD is not linear, even under treatment, detection of new-onset psychiatric disorders is also important because of their high impact over the treatment plan. Therefore, using structured clinical interviews during the first 6-12 months of the treatment is also recommended.

Monitoring treatment efficacy in PTSD using standardized instruments is strongly encouraged. For this purpose, we recommend validated scales, inventories, or structured interviews, like the Clinician-Administered PTSD Scale for DSM-5 (CAPS-5), PTSD Symptom Scale Interview (PSS-I), Mississippi Scale for Combat-related PTSD (MISS) [53-55]. This is considered a good clinical practice because it may increase the objectivity of the psychiatric evaluation, although it is not specifically recommended in all the reviewed therapeutic guidelines.

We consider good clinical practice in the PTSD treatment to actively monitor the tolerability of the pharmacological treatment, to detect early adverse events that may decrease therapeutic adherence [56]. For this purpose, the administration of the Treatment Satisfaction Questionnaire for Medication (TSQM) [57] or a simpler visual analogic scale for self-evaluation is considered useful.

CONCLUSIONS

A review of the existing therapeutic guidelines focused on PTSD management detected several common recommendations. These refer to the use of CBT and related therapies and EMDR as a first-line approach and SSRIs or venlafaxine as the main pharmacologic agents [1-5, 11]. Our team has added as good practice recommendations the necessity to use validated instruments for initial and follow-up diagnostic evaluations, as well as the monitoring of treatment tolerability and efficacy. Because of the high rate of comorbid disorders in PTSD patients, the case manager should be alert to new-onset psychiatric disorders that may appear as complications or just comorbidities in this population.

An integrated, psychological, and pharmacological approach should be considered for these patients, with frequent follow-up visits, and emergent disorders have to be integrated into the case management plan as soon as they are detected.

Demons-Meigs syndrome – Diagnosis and therapeutic conduct

Ioana A. Negoiță[1], Bogdan P. Panaite[2,3], Mihnea Nicodin[2], Florin Năftănăilă-Mali[2], Elena D. Soloman-Năftănăilă-Mali[2], Nicolae Niculescu[2], Ioana M. Cobani[2], Andreea Kalamar[4]

Abstract: *Demons-Meigs syndrome is a rare benign pathology that can be confused with other benign and malignant pathologies. The clinical picture is marked by an increase in abdominal volume, pelvic-abdominal pain, but it can also be associated with breathing difficulties due to excess ascites fluid and pleurisy. Imaging paraclinical examination easily reveals the three components: ascites, pleurisy, and ovarian mass.*

Surgical treatment helps to relieve symptoms in a relatively short time.

Keywords: *Meigs, ovarian tumor, imaging examinations*

INTRODUCTION

Demons-Meigs syndrome is represented by three elements: benign ovarian tumor – fibroids, ascites, and pleural effusion. Most often, it is a diagnosis of exclusion. Sometimes, the ovarian tumor can also be represented by thecoma, fibrothecoma, granular cell tumor, less often Brenner tumor. The prevalence and incidence of this syndrome are not fully known; an increase proportional to age was observed, the average of this pathology being around 50 years of age. At the same time, cases of pseudo-Demons-Meigs syndrome were reported in prepuberty in which the benign tumor was represented by another type of ovarian tumor formation (teratoma or cystadenoma). Of the ovarian masses surgically excluded, a percentage between 2 and 5% is represented by ovarian fibroids, and only 1-2% of them meet the criteria necessary for Demons-Meigs syndrome [1].

Demons-Meigs syndrome was first described in 1937 by gynecologist Joe Vicent Meigs, professor at Harvard Medical School, and by the pulmonologist John Class, in the American Journal of Obstetrics and Gynecology. The name Demons associated with the syndrome is given by Albert Jean Octave Demons, in 1887, when he communicates 9 cases of ovarian tumors that associate ascites fluid and hydrothorax [1].

Demons-Meigs syndrome involves the remission of ascites and pleural fluid when a benign ovarian tumor is surgically excluded – this fact is noticed and established by Albert Jean Octave Demons in 1903. Life expectancy after surgical treatment is the same as that of the general population [1].

Ascites was found in 10-15% of patients with ovarian fibromatous formations, while pleural fluid was identified in 1% of them. Pleural effusion is frequently located on the right side – in about 70%, while in 15% it is located on the left or bilateral side [1, 2].

[1] Carol Davila University of Medicine and Pharmacy, Bucharest, Romania
[2] Carol Davila University Central Emergency Military Hospital, Bucharest, Romania
[3] Titu Maiorescu University, Bucharest, Romania
[4] St Ioan Emergency Clinical Hospital, Bucharest, Romania

In addition to this syndrome, the pseudo-Demons-Meigs syndrome has been described, in which, along with ascites and hydrothorax, there is another benign ovarian tumor such as struma ovarii tumor, a teratoma, or a mucinous cystadenoma. The associated tumor may also belong to the salpinx, uterus, or may be a distant metastasis or a gastrointestinal tumor.

Ovarian tumors can be classified into germ cell tumors, gonadal germ cell tumors, and surface epithelial tumors [2].

Germ cell tumors account for 10-15% of all ovarian tumors and can be classified: (mature and immature) teratoma, dysgerminoma, gonadoblastoma, embryonal carcinoma, non-gestational choriocarcinoma. Only mature teratoma and gonadoblastoma are benign tumors [2].

The group of sex cord-stromal tumors includes granular cell tumors, fibroids-thecoma group (95% benign), Sertoli-Leydig cell tumors (5% malignant), gynandroblastoma (always malignant), and steroid cell tumors (70% benign).

Surface epithelial-stromal tumors come from the coelomic epithelium and account for 80-85% of all ovarian tumors. They include serous and mucinous cystadenoma (80-85 % benign), endometrioid tumors, clear cell tumors (which are 95-98% malignant), and Brenner tumor (benign in 98% of cases) [2].

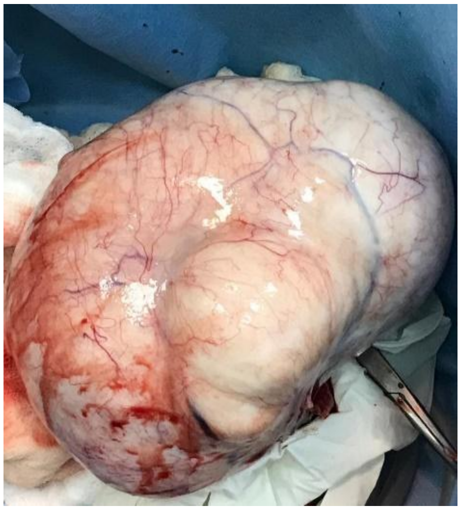
PHYSIOPATHOLOGY

The etiology of ascitic fluid is poorly understood. A possible explanation for its appearance is due to the phenomenon of peritoneal irritation caused by ovarian fibroids. Also, the ovarian tumor could favor the appearance of ascites by the effect on the surrounding vessels represented by both the lymphatic vessels and capillaries. Another explanation would be the discharge of certain cytokines and interleukins that would increase capillary permeability, the result being ascites. Other hypotheses suggest that ovarian tumor torsion or hormonal stimulation may cause ascites. Many authors claim that tumors with an increased diameter of more than 10 cm could stimulate the secretion of ascitic fluid [2, 3].

The etiology of hydrothorax is unclear. The accumulation of pleural fluid is frequently on the right side, but can also be on the left or bilateral side. It is speculated that it was due to the transfer through the transdiaphragmatic lymphatics from the ascitic fluid. The amount of pleural fluid is directly proportional to that of ascitic fluid. The blockage of transdiaphragmatic lymphatics has been found to prevent pleural fluid from accumulating, while the amount of ascitic fluid increases [3].

It has been shown that both ascitic and pleural fluid can be exudative (rich in protein, caused by increased membrane permeability due to inflammation) and transudative (low in protein, by the increase of the hydrostatic pressure and decrease of the colloid osmotic pressure). However, pleural fluid is often exudative. Electrophoresis has shown that pleural fluid and ascitic fluid are of the same nature [3].

Figure 1: Giant ovarian fibroids. A 69-year-old woman who was brought to the Emergency Room of the Central Military Emergency University Hospital for altered general condition, dyspnea with orthopnea, loss of appetite, and enlarged abdominal volume, CA 125 is dosed – it's the value being 2317.7 U/mL



The signs and symptoms of this etiology include altered general condition, physical asthenia, fatigue, dry cough, weight gain, or loss. Among the gynecological signs and symptoms found in Meigs syndrome is amenorrhea, menstrual disorders (menometrorrhagia for women in the perimenopause period or metrorrhagia in the climax), iron deficiency anemia. A unilateral abdominal ovarian mass may be found, more often on the left or bilateral side, solid, asymptomatic, or symptomatic due to the presence of abdominal-pelvic pain, mass effect on surrounding organs [4].

The appearance of ascitic fluid generates abdominal distension, dyspeptic disorders (nausea and vomiting) due to increased intra-abdominal pressure, and constipation.

The appearance of pleural fluid leads to tachycardia, tachypnea, dyspnea with orthopnea, the abolition of the transmission of vocal vibrations, decrease or reduction of vesicular murmur, declivitous dullness to percussion. Pleural effusion is more common on the right side, may be exudative, protein-rich, or transudative. In the case of diagnosis or evacuation paracentesis or thoracentesis, it is found that the fluid does not contain malignant cells even if it is exudative or transudative [5].

The differential diagnosis of Demons-Meigs syndrome is broad and includes benign and malignant pathologies, and most often it is a diagnosis of exclusion.

The main differential diagnosis is with ovarian neoplasm, metastases from a breast neoplasm, colorectal, liver failure, nephrotic syndrome, Milroy's disease, tuberculosis, lung cancer, gastrointestinal tumors.

LABORATORY TESTS

The blood count shows information about hemoglobin, platelet count, and hematocrit. If the hemoglobin level is low, further investigations may be performed including syderemia, ferritin, total iron-binding capacity, and reticulocyte count. Iron deficiency anemia may require iron therapy before surgery or in more severe cases may be corrected by blood transfusion. Treatment with iron-containing supplements is continued postoperatively.

Carrying out clotting time is imperative before surgery. The ionogram is determined by checking and correcting any anomalies [1, 4].

Thoracentesis and paracentesis indicate whether the nature of the fluid is exudative or transudative type, and the cytological examination refutes the existence of malignant cells.

One blood biomarker used is CA 125. It is the antigenic representative of a 220-kD glycoprotein, and the physiological sources are represented by the coelomic epithelium and derivatives: pleura, pericardium, peritoneum as well as the epithelium of the fallopian tubes, endometrium, endocervix. Elevated values of this biomarker can be found in pregnancy, ovarian neoplasm, uterine fibromatosis, endometriosis, pelvic inflammatory disease, cancer of the fallopian tubes, but also in other non-gynecological pathologies (liver failure, kidney failure, autoimmune diseases) [5, 6].

In Demons-Meigs syndrome, there is an increase in the value of CA 125 which does not correlate in this case with the malignancy and which remits after the surgical exclusion of ovarian fibroids.

IMAGING EXPLORATIONS

Ultrasound is an investigation that detects tumor mass. The ultrasound appearance depends on the degree of compromise of vascularity, ovarian formations, and the presence or absence of adnexal hemorrhages. Ultrasound is the method of choice for symptomatic women but is limited in differentiating an ovarian lesion from a para ovarian one.

The radiography confirms and quantifies the existence of pleural effusion.

Figure 2: CT sections in the coronal plane. Tumor formation with probably left ovarian starting point, which includes tissue areas and areas of necrosis; ascitic fluid in increased amounts.

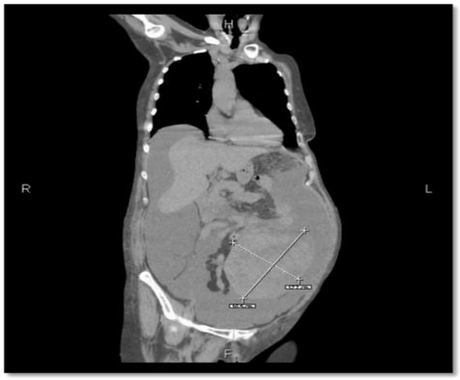


Figure 3: CT sections in the axial plane. Tumor formation with probably left ovarian starting point, which includes tissue areas and areas of necrosis; ascitic fluid in increased amounts.

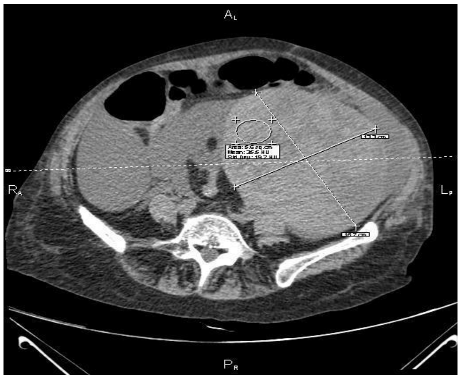

Figure 4: CT section of the thoracic region in the axial plane, parenchymal window. Accentuation of the interstitial lung disease and left pleural effusion.

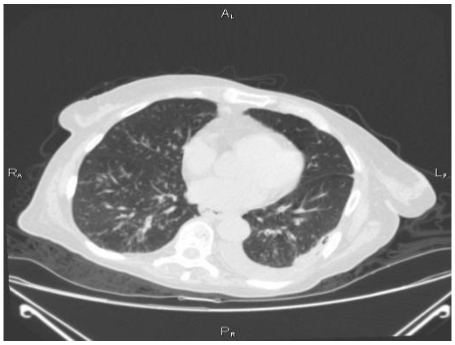

CT exploration of the abdomen and pelvis is a quick way to explore with great accuracy. Serial images formed during the exploration can be viewed on a screen, stored, and with them, three-dimensional reconstructions can be obtained, that provide precise details about the location of the tumor, vascular intake, but also useful information for the surgical approach. It can be done natively or after injecting an intravenous contrast-enhancing agent. CT examination may also be helpful when attempting tumor punch biopsy. The risks associated with this investigation are the cumulative effect of radiation. CT examination is contraindicated in pregnancy. Contrast enhancing agent allergy allows only the performance of native CT. Kidney failure is also a contraindication to the administration of the contrast-enhancing agent. In Demons-Meigs syndrome, CT examination confirms the existence of pleural fluid, ascitic fluid, ovarian tumor mass, and excludes distant metastases or the existence of other neoplasms [7, 8].

Figure 5: CT sections in the axial plane. Heterodense tumor formation with tissue structures and areas of necrosis included, clearly delimited, developed ilio-pelvic on the left side.

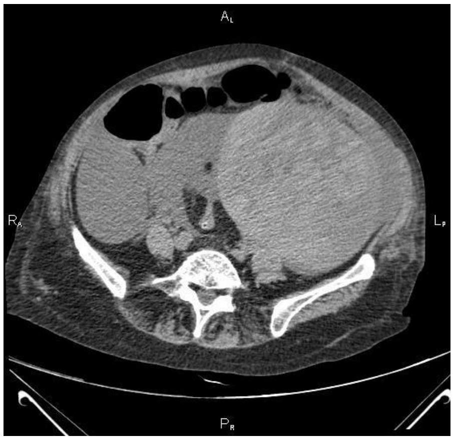

Figure 6: CT sections in the axial and sagittal plane. Heterodense tumor formation with tissue structures and areas of necrosis included, clearly delimited, developed ilio-pelvic on the left side.

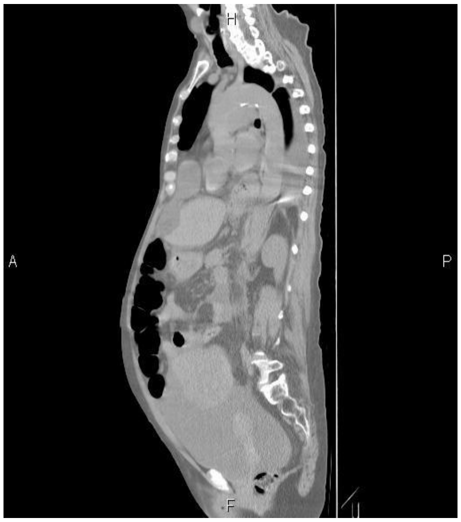

Figure 7: CT section of the upper abdomen in the axial plane. Fat densifications in the supramesocolic space.

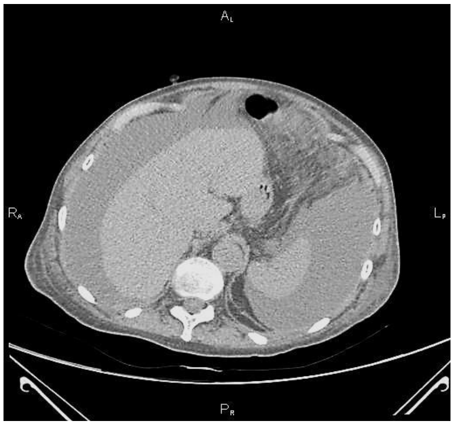
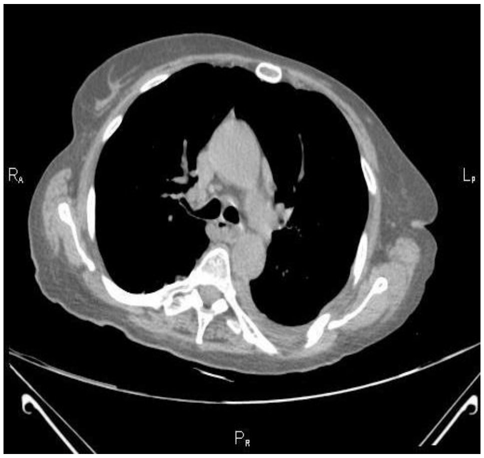


Magnetic resonance imaging characterizes suspicious adnexal masses, establishes ovarian affiliation in inconclusive ultrasound cases, argues in favor of benignity or malignancy of ovarian tumor mass, and specifies other associated abnormalities – peritoneal carcinomatosis, adenopathies.

Figure 8: CT section in the axial plane in the mediastinum. No mediastinal tumor adenomegalies; left pleurisy.

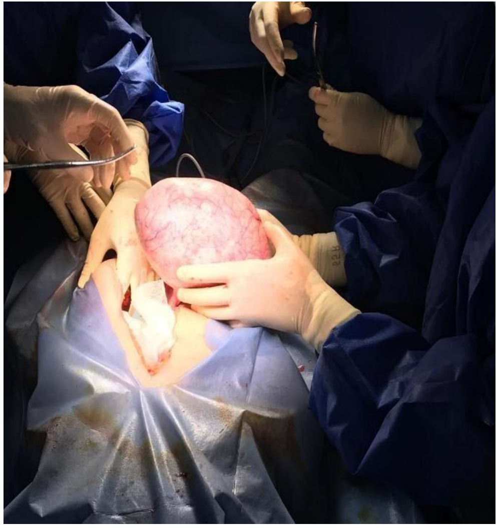


TREATMENT

The treatment of Demons-Meigs syndrome is surgical and is represented by exploratory laparotomy with surgical staging. Biopsy of ovarian mass, omentum, and lymph nodes that reveal benign nature can be performed [7, 9].

If the patient is in the prepubertal period, tumorectomy, partial oophorectomy, and unilateral salpingectomy are used. In women of childbearing potential, surgical treatment involves unilateral adnexectomy. Surgical treatment of menopausal patients may include total hysterectomy with bilateral adnexectomy [7, 8].

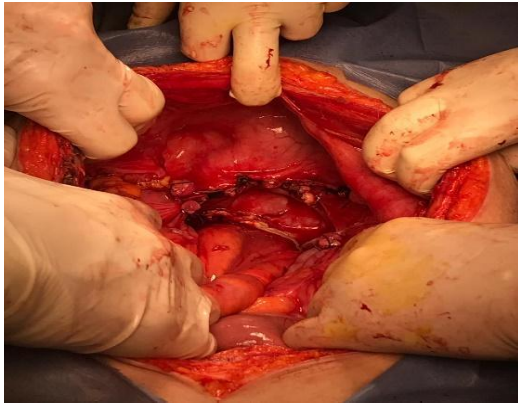
Figure 9: Woman 69-year-old – intraoperative: ascitic fluid is found (approximately 500 ml which is collected and sent for histopathological examination); fibroid uterus; right adnexa modified according to age, and at the level of the left adnexa a tumor formation with dimensions of 18/14/10 cm, firm consistency, white-yellowish color, irregular, pedunculated shape. Total hysterectomy with bilateral adnexectomy is performed (with the sending of the samples to anatomopathological examination).



If the patient is in the prepubertal period, tumorectomy, partial oophorectomy, and unilateral salpingectomy are used. In women of childbearing potential, surgical treatment involves unilateral adnexectomy. Surgical treatment of menopausal patients may include total hysterectomy with bilateral adnexectomy.

The cure rate is high and no recurrences have been reported after the disappearance of the ovarian tumor. Ascites and pleural effusion disappear within a few weeks after surgical exclusion of the pelvic mass [7, 8].

Figure 10: Intraoperative image after total hysterectomy with bilateral abdominal adnexectomy for giant ovarian fibroids. The postoperative evolution was favorable under antibiotic, anticoagulant, anti-inflammatory treatment, and the treatment of the underlying pathology. Gradual remission of postoperative ascites and pleurisy was noticed.



CONCLUSIONS

Demons-Meigs syndrome is defined by ovarian tumor with pleural effusion and ascites. Ovarian tumor is benign and is usually ovarian fibroids. After excluding the ovarian tumor, ascites, and pleural effusion remit. CA 125 tumor marker has elevated values similar to ovarian cancers, but values return to normal after surgical treatment. Even though this syndrome has been described for more than 100 years, it still poses problems in diagnosis, having an uncharacteristic picture. Molecular, hormonal, genetic, and mechanical factors are involved in its etiopathogenic mechanism.

The only treatment available for the remission of symptoms is surgery.

VARIA

Desert malaria "Curse of the Thar Desert" – a unique geographical endemicity of malaria and combating it with modern technology

V.S. Srikanth[1], G. Geethanjali[2], Cibi Manoharan[3], Varsha Somakumar[4]

Abstract: *Introduction: This study focuses on the Malaria endemic in the Thar Desert- The most populated desert in the world. Malarial endemicity in a desert environment is a unique and rare geographical presentation, as malaria is usually common in areas where there is rainfall and water stagnation - like ponds, fields, etc. In this study, we want to highlight the unique clinical presentation, lab findings, and reason behind the existence of malaria in the desert. Most importantly we also would like to share our innovative idea to eliminate breeding sites using Quadcopters and drones.*

Materials and methods: Study type – Prospective observation study, Study duration – October 2020 to December 2020, Sample size-103 cases, Inclusion criteria – all smear-positive Malaria cases, Exclusion criteria – Cases Referred to higher centers because of complications.Tools used for breeding site identification – Quadcopters and Drones with HD cameras. Since the area to be surveyed was vast (>30km), it was very difficult to do a manual survey in the harsh desert climate. The patients' demographics, Clinical Presentations, and laboratory parameters were collected systematically in a predesigned format and entered into an excel sheet. The finding of our study was compared with the malaria cases from different parts of the country.

Results: All malaria was identified as Plasmodium vivax. The mean age group was 36 years (min-21 and max-56). Clinical features- out of 103 cases, 78% of the patients presented with all 4 symptoms of fever, chills, headache, and bodyache.22% presented with atypical isolated symptoms of abdominal pain, vomiting, myalgia, severe joint pain. 77% of patients had mild hepatosplenomegaly, 7 patients presented with hypotension, and 2 were in sepsis. Lab parameters – 88% of the patients had anemia, of which 5% had severe anemia, 40% had leucopenia while 6% had leucocytosis.87%had thrombocytopenia, out of which 56% had a platelet count less than 50,000/ml. 2% had mild AKI, bilirubin levels were elevated in 53%, and 36% had transaminitis. Using technology, the survey of the entire area was done in 1 week and all the breeding sites were eliminated on the same day of identification and a drastic drop in malaria cases was noted.

Conclusion: We conclude that desert malarial presentation of Plasmodium vivax is unique in clinical presentation and lab derangements compared to other malarial cases. Usage of technology like quadcopters and drones for breeding site identification played a major role in curtailing cases drastically in a very short period in an effective way.

Keywords: *desert malaria, Plasmodium vivax, drone surveillance for breeding site*

INTRODUCTION

Desert Malaria, yes you have read it right! As commonsense dictates, malaria is common in tropical countries and areas, where the mosquito breeding site is more commonly seen in places where water gets stagnated during the rainy season, e.g., ponds, ditches, and marshy areas which serve as a

---

[1] 15 Air force Hospital Jaisalmer, India
[2] Ramachandra Medical College, India
[3] Ganga Hospital, Coimbatore, India
[4] Amrita Institute of Medical Sciences, India

temporary breeding ground for mosquitoes. Malarial endemicity in a desert environment is a unique and rare geographical presentation of this disease.

The Great Desert of Thar is the most widely populated desert in the world, with a population density of 83 people per km^2, which is located in the northwestern part of India [1]. Desert ecosystem, which has its peculiarities to offer, is yet another operating system for malaria.

Malaria is one of the oldest diseases known to mankind. In ancient India, malaria was described in The Compendium of Sushruta, a Sanskrit medical treatise. The World malaria report 2019 estimates that globally, there were an estimated 228 million cases of malaria in 89 countries. The estimated number of malaria deaths in 2018 and 2019 stood at 411,000 lives in 2018 and 409,000 lives in 2019 respectively [2]. In 2012, it was estimated that the total economic burden of malaria in India was around US$ 1940 million, with 75% from lost earnings and 25% from treatment costs borne by households. Besides saving lives, eliminating malaria in India would also avert these socioeconomic losses [3].

Malaria is caused by a protozoan parasite, Plasmodium, and transmitted by the vector anopheline mosquitoes. Malaria parasite in India has two major human malaria species, Plasmodium falciparum, and P. vivax. Approximately 65% of those at risk for becoming infected with malaria in Southeast Asia are individuals residing in India (WHO 2010). The central and eastern regions of India report the most malaria. An. culicifacies is responsible for 60–65% of the malaria burden [4]. The three most important challenges for malaria control in India are difficulties in control implementation and logistics, insecticide resistance, and antimalarial drug resistance. Being the world's second-most populous country, and having a faster rate of urbanization, adds to the challenges. India contributes 77% of total malaria in Southeast Asia. Multi-organ involvement/dysfunction is reported in both Plasmodium falciparum and P. vivax cases [4]. In this study, we did a detailed analysis of the unique presentation of desert malaria and compared it with other studies of malaria presentation in a tropical ecosystem.

MATERIALS AND METHODS

This is a prospective study done from Oct to Dec 2020, where 103 cases of malaria cases were studied.

Inclusion criteria – all smear-positive malarial cases

Exclusion criteria – cases referred to higher centers because of complications.

Patients' demographics, clinical presentations, and laboratory parameters were collected in a systematic method and the collected data was analyzed in windows excel sheet.

For malarial surveillance, we had used quadcopters and drones with HD cameras for regular and periodic surveillance, as it was very difficult to do breeding site surveillance manually due to the extreme temperatures and scattered sites.

The photos from the drone and quadcopters were collected and given to the respective head of units in the areas and necessary action was taken within 24 hours of target identification to eliminate the breeding sites.

RESULTS

103 diagnosed cases of plasmodium vivax malaria were admitted, out of which all were males. The minimum and maximum age of the patients reported was 21 and 56 respectively, with a mean age group of 36 years. Duration of the hospital stay ranged from a minimum of 2 to a maximum of 18 days.

The average temperature of the patients was 101.5 F, maximum temp was 103 F. 78% of the patients presented with all 4 symptoms of fever, chills, headache, and body ache. 22% presented with atypical isolated symptoms of abdominal pain, vomiting, myalgia, severe joint pain. 77% of patients had mild hepatosplenomegaly, 7 patients presented with hypotension, and 2 were in sepsis.

Lab parameters – 88% of the patients had anemia (Hb 9-11 g%), of which 5% had severe anemia (6.5-8.5 g%), 40% had leucopenia while 6% had leucocytosis. 87% had thrombocytopenia, out of which 56% had a platelet count less than 50,000/ml. 2% had mild AKI, bilirubin levels were elevated in 53%, and 36% had transaminitis.

Using technology, the survey of the entire area was done in 1 week and all the breeding sites were eliminated on the same day of identification and a drastic drop in malaria cases was noted. It was a very effective and time-saving modality.

Figures 2 and 3 show open tanks on the roofs of apartment buildings, as well as abandoned open manholes behind these buildings where people don't frequent and were therefore unnoticed by the residents.

One of the main breeding sites of Anopheles could also be the long canals that run for kilometers through the desert, providing a haven for the larvae, as shown in Figure 4.

DISCUSSION

Our results were comparable to that of a study done in south India by Madhu Muddaiahet al. [5], in which males (81%)

outnumbered females (19%) and Plasmodium vivax was the major parasite type (52.54%). In their study incidence of malaria increased from June onwards coinciding with monsoon season, contrary to our study, where caseload was more in October-December. A study by Pankajala Amritha et al. [6], also had 94.71% of P. Vivax cases, and the mean duration of hospital stay was 5.17±3.31 days.

Figure 1: The area identified using a quadcopter. The area seen in the photo was highly inaccessible; Red arrow marks show the sites of waterlogging and the Yellow outlines show the breeding sites of Anopheles mosquito where the larva develops, and the shady environment gives mosquito cover from the extremely hot weather

In a multicentre study done in Columbia [7], 92.5% of patients presented with fever, chills, headache, sweating, myalgia/ arthralgia, similar to our study. Mild hepatomegaly and splenomegaly as well as abnormal transaminases were mostly observed in P. vivax malaria patients.

A meta-analysis of malarial cases in Malaysia and Australia by Cho Naing et al. [8] provided evidence of the clinical relevance of severe thrombocytopaenia in P. vivax malaria which was in line with our result. In our study thrombocytopenia, anemia, and altered liver function were seen, contrary to study results found by Wajihullah Khan et al. [9] where anemia, jaundice, convulsions, and acute renal failure were significantly high (3-4 times) in subjects infected with P. falciparum than with vivax.

But a in study done in AIIMS Rishikesh by Jagdish Prasad Goyal et al. [10], there was no statistically significant difference found in complications such as anemia and thrombocytopenia between P. vivax and P. falciparum. Similarly in a Columbian study [11], anemia and thrombocytopenia were common in both.

A study was done in Aligarh Muslim University [12] in central India also showed that in P. falciparum infection, the incidences of anemia, splenomegaly, renal and liver dysfunction, and jaundice were higher compared to those in P. vivax infection. Several complications such as acute kidney injury, jaundice, severe anemia, metabolic acidosis, shock, hyperpyrexia, hypoglycemia, generalized tonic-clonic convulsions, etc. were found to be more prevalent in patients with P. vivax infection. These symptoms were until recently known to be associated with falciparum malaria [13].

Malarial surveillance programs by the government are adversely affected by an insufficient number of sanctioned posts of health workers and other program staff in different parts of the country. For instance, there are about 40000 multipurpose health workers (MPWs) against approximately 80 000 sanctioned posts for nearly 150000 sub-centers (SCs) across the country [14]. Over the past fifteen years, the fight against malaria improved dramatically. Insecticide-treated bed nets and indoor residual spraying resulted in an enormous reduction in the number of children dying of the disease [15]. Unfortunately, it is not enough.

For the first time, drones were tested to help fight malaria in Tanzania, on the island of Zanzibar, off the coast of Mozambique. High-tech 'Anti-Malaria Drones' drones were used to spray a silicone-based liquid gel (Aquatain) in endemic areas where malaria-carrying mosquitoes lay eggs, and where there are large concentrations of stagnant water with the hope that the new substance will stop mosquitoes' eggs from hatching. It is part of a program by the Zanzibar government, looking towards eliminating malaria by 2030 [16].

CONCLUSION

We conclude that desert malarial presentation of Plasmodium vivax is unique in its clinical presentation and lab derangements compared to other malarial cases. Doing manual surveillance for breeding sites is very difficult because of the large areas to be covered, the time involved, and the requirement of a lot of manpower. Using drones and quadcopters is a cost and time-effective method which helps in the very early identification and eradication of breeding sites.

VARIA

Determine the medical causes and diseases which led to early and permanent medical disqualification of military cadets

Azade A. Farahani[1], **Hamze Shahali**[2]

Abstract: *Background and Aim: Efficient manpower is the most important of military capital, and many studies have shown the relationship between personal health and organizational performance. The preparation of military cadet volunteers to enter aeronautical training and the provision of optimal services in the form of well-trained pilots requires many material spiritual resources that disabilities, make them waste.*

Methods: This is a descriptive, cross-sectional, retrospective study with target population of Iranian air force cadets with early and permanent medical disqualification from 1986 to 2016.

Results: 80 cases were detected, including 25 kills and 55 early and permanent medical disqualification. The main causes were ear, nose and throat, psychiatry and cardiac, respectively. Common diseases include motion sickness, generalized anxiety disorder, adjustment disorder and epilepsy, respectively. The total number of lost service years was 1412 person years and the average of lost service years was 25.67 person years. Most of the lost service years were related to medical causes included ear, nose and throat, psychiatric and cardiac, and diseases included motion sickness, generalized anxiety disorder and adjustment disorder, respectively. Neurologic causes resulted in highest average of lost service years and high blood pressure was the major diseases, respectively.

Conclusions: Due to the lack of similar studies, the results of this study were compared with the data, which extracted from previous studies in the pilot's population. Because of occupational similarity between pilots and cadets, It was expected that the most common causes in pilots and cadets should be the same, but we found that the results are very different.

Keywords: *disabilities, medical disqualification, health, performance, prevention*

INTRODUCTION

Personal resources are the most important capital of armed forces, and many studies have shown the strong links between personal health and organizational performance. In order to increase productivity, organizations have anticipated numerous measures to evaluate pre-employment health and staff health during service. However, health risks remain the most important reducing factor for personal productivity. Disability is defined as the effect of a disorder on physical, mental, and social activity of a person and the work environment and family status are also effective elements. [1, 2, 3] Cadets are the future capital for professional aviation and the sufficient understanding of the medical causes and diseases leading to their early and permanent medical disqualification (EPMD), plays an important role in professional pilot training. According to statics, effective prevention of cardiovascular risk factors in aviation population has a significant role in improving the professional health index of pilots. The study of pilot's work environment and their lifestyle, active intervention, periodic

Corresponding author: HamzeShahali
hamze.shahali@ajaums.ac.ir

regular examinations and screening test for early detection of diseases are among the basic measures. [9] Preparation of cadets to enter pilot's training courses and delivering desirable services in the form of expert military pilots requires 10 million dollars and extreme spiritual costs, and as a result disqualification, it will be a major loss of money and human budget for armed forces [21]. Thus, control of this dilemma has no way except of effective prevention. [1-5]

These days, the economic, mental and social problems caused by morbidity and mortality of armed forces are critical burdens. Regardless of the huge cost to run and maintain of powerful army, the financial and psychological burden of the victims can be devastating for any society. [20] In 1993, the United States army paid 500 million dollars to newly recruited armed forces. [6-7] In a study between 1980 and 1994 on the causes of disability in US air and sea forces, it has been shown that the disable armed forces has led to an excessive cost in about 1.5 million dollars for US army. [1] The federal aviation association(FAA) has conducted a great comprehensive study in 2014 on the causes of medical disqualification for pilots whose results indicate fifteen causes include pectoris angina, bipolar mood disorder, cardiac valve replacement, coronary artery diseases, diabetes mellitus, loss of consciousness with unknown reason, seizure, cardiac replacement, myocardial infarction, permanent pace maker, disabling personal disorder, psychosis, drug abuse and dependency and lack of neural control, respectively. [15] Cadets are the future maker of aviation and can become expert pilots in near future. Unfortunately, so far, there has not been a similar published study in the world, which makes it necessary to accomplish this research more effective and strategic.

The ultimate goal of this study was to determine the causes and diseases which led to EPMD of Iranian Air Force (IRIAF) cadets from 1986 to 2016. Other objectives include determining the exact numbers of cadet and aviation trainee kills in IRIAF, determining the lost service years (LSY) in IRIAF cadets with EPMD (with counting of seven years of aviation training course and a total service duration of 30 years in IRIAF), determination of the average LSY for IRIAF cadets with EPMD and the provision of scientific and practical solution to prevent the EPMD of IRIAF cadets.

METHODS

This study is a descriptive-cross sectional-retrospective research that its target population was the IRIAF cadets with EPMD from 1986 to 2016. IRIAF cadets with medical disqualification from 1986 to 2016, that their relevant official documents have been recorded in medical sessions and their medical profiles were included, but cadets with disqualification due to physical or mental illness and death in non-occupational accidents, non-medical reasons, personal requests or disciplinary punishments were excluded from study.

The ethical approval of this study was issued with registration No: 1016794 by the Ethics Committee of the Aerospace and diving medical faculty in Aja University of medical sciences. This study was conducted by the personal expense of the corresponding author and so, no governmental or military fund was not be used at all.

After obtaining administrative licenses (Allow access to information) and ethics approval (being ethical and maintaining the principle of patient privacy) in research ethics council of aerospace and diving medical faculty (which is subset of AJA University of medical sciences) and coordination with relevant authorities in IRIAF department of health, medical education and services for obtain permission of unlimited access to medical profiles and sessions, in order to maintain the medical confidentiality, the archivist assigned a secret and random code to each participant that was recorded on top of the electronic data forms. Required information including age, year of entry to and excite from service, main medical cause and disease which led to EPMD were inserted in an electronic form designed according to the study requirements. An individual archivist was used to enter data and in order to military and national information security, the total number of IRIAF cadets was not stated.

All of the IRIAF cadets were male and, in few cases, which there were more than one reason for EPMD, only the main cause was considered. Like other similar studies, all medical causes and diseases were classified based on the 10th version of international classification of diseases (ICD-10) and the causes in domain of nephrology and urology have been recorded as renal causes. However, possible differences in the statistics of similar studies may be related to their classification methods for causes and diseases. It should be noted that in any armed force, while training or real battle, casualties are inevitable and so killed cadets are not considered to be among the lost years of service. The data was collected and analyzed by the researcher using Microsoft office software (version 2016) and compared with the results of similar studies in pilot's population.

RESULTS

During the period from 1986 to 2016, 80 cases of early and permanent discharges were obtained from all the medical sessions and medical profiles, including 25(31.25%) kills and

55(67.75%) medical disqualification. The kills also included 17 cadets and 8 aviation trainees. This data are given in Table1.

Table1: Study Data

Occupation	Early and Permanent Discharge	Kills
Cadets	55	17
Aviation Trainees	0	8

Common causes of EPMD in IRIAF cadets included ear, nose and throat (ENT), psychiatric and cardiac, respectively. Their prevalence is depicted in Figure1. Common diseases resulted in EPMD of IRIAF cadets included motion sickness, adjustment disorder, epilepsy and, respectively and shown in Table2.

Figure 1: Causes lead to the EPMD of IRIAF cadets

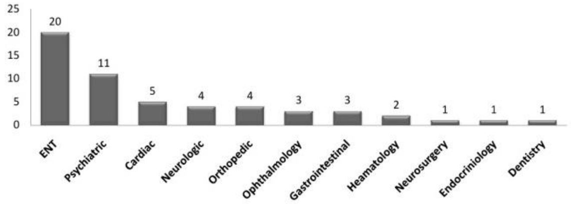

Table 2: Diseases lead to EPMD of IRIAF Cadets

Diseases	Motion Sickness	Generalized Anxiety Disorder	Adjustment Disorder	Epilepsy	High Blood Pressure	Others
N#	18	5	3	3	2	24

As 1412 LSY in IRIAF cadets, the most common causes include ENT, psychiatry and cardiac, respectively. More detail is on Figure2.Common diseases with most of LSY include motion sickness, generalized anxiety disorder, epilepsy, adjustment disorder, and high blood pressure, with detailed statistics in Table 3.

Figure 2: LSY of IRIAF cadets with EPMD according to causes

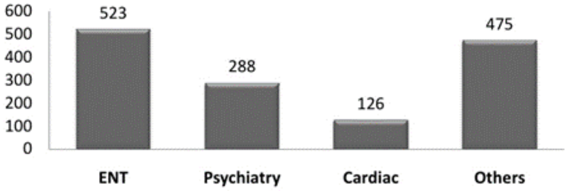

Table3: LSY of IRIAF Cadets with EPMD According to Diseases

Diseases	LSY
Motion Sickness	468
Generalized Anxiety Disorder	137
Epilepsy	82
Adjustment Disorder	74
High Blood Pressure	57
Others	594

The average of LSY in IRIAF cadets with EPMD was 25.67 person years (p/y), the frequency o which based on common causes, including neurology, psychology and ENT with comprehensive information shown in Figure3.

Common diseases resulted in the highest average of LSY in IRIAF cadets with EPMD including high blood pressure, occupational hearing loss, generalized anxiety disorder, epilepsy, and borderline personality disorder, as shown in Table4.

Figure 3: Average LSY of IRIAF cadets with EPMD according to causes

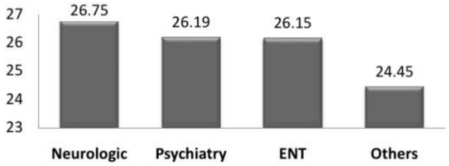

Table4: Average LSY of IRIAF Cadets with EPMD According to Diseases

Diseases	Average of LSY
High Blood Pressure	28.5
Occupational Hearing Loss	27.5
Generalized Anxiety Disorder	27.4
Epilepsy	27.33
Borderline Personality Disorder	26.5
Others	24

DISCUSSION

So far, there has been no investigation into the causes and diseases that lead to EPMD of military or civil cadets in Iran or the world. Therefore, in order to compare the results of this study, the studies in civil and military pilot's population were used, because cadets and pilots have similar occupational and social status. The main reasons for EPMD in IRIAF cadets during our study included ENT, psychiatric, and cardiac, respectively. In the study of Whitton-1984 on United State Air Force (USAF) pilots and navigators, common causes were cardiac and neurologic [16], while in the same study of Mc Crary-2002, the most common causes in 1995 to 1999, include cardiac, musculoskeletal, neurologic and endocrinology. [11] Also, in the study of Montazeri-2005, the most common causes of EPMD in IRIAF pilots included cardiac and musculoskeletal. [19] In the study of Ghazizade-2010 on the same population in 1992 to 2003, cardiac, nervous-skeletal and gastrointestinal were the most common causes. [18]

In the Dark study with the help of FAA, on medical disqualification of American airlines pilots in 1983 and 1984, the most commonly reported causes were cardiovascular and Neuropsychiatric events. [18] In the Nakanishi study on permanent disability of 260 Japanese crews, significant causes include malignancies, neurodegenerative, cardiovascular, gastrointestinal and musculoskeletal disorders. [8] In the review of trained pilots on Commonwealth countries from 1994 to 2004, the causes of cardiovascular were prevalent. [18] In the Arva study on 257 Norwegian civil pilots, the main causes were cardiovascular, neurologic, musculoskeletal and psychiatric disorders. [10] In the studies of Mitchell-2004 and Evan-2006 on sudden incapacitation of British civil pilots, 36 cases have been diagnosed and half of them were due to cardiac and cerebrovascular disorders and psychiatric disorders have been one of the leading causes. [12, 13] In the Nezami study on 200 civil pilots of Vnukovo airport in Moscow, cardiac, neurologic and digestive have been the main causes of medical disqualification. [9] Common diseases resulted in EPMD of IRIAF cadets, including motion sickness, generalized anxiety disorder, adjustment disorder, epilepsy and high blood pressure. In the Mc crary's review on USAF pilots and navigators in 1995 to 1999, more common diseases were ischemic heart diseases, high blood pressure, back pain, inter vertebral disc disorders and migraine. [11] In the study of Nezami on 200 civil pilots of Vnukovo airport in Moscow, ischemic heart diseases, myocardial infarction, high blood pressure, cerebrovascular sclerotic lesions and peptic ulcer have been common. [9]

The LSY was 1412 (p/y) and the highest was related to ENT, psychiatric and cardiovascular causes, respectively. Diseases with the highest LSY included motion sickness, generalized anxiety disorder, epilepsy, adjustment disorder and high blood pressure. The average of LSY was 25.67 (p/y) and the highest was related to neurologic, psychiatric and ENT causes, respectively. Diseases with the highest average of LSY included high blood pressure, occupational hearing loss, generalized anxiety disorder, epilepsy and borderline personality disorder. In the study of Montazeri-2005, the mean LSY of IRIAF retireds with EPMD was 6.5(p/y). [19] In the Ghazizade study on IRIAF medical disables from 1992 to 2003, the mean LSY was 6.14 (p/y) and the highest was 10 (p/y). [18]

This study, like other studies, has limitations that include: 1) the lack of a comprehensive electronic system for record of medical profile, 2) the possibility of oriented malingering in disorders which have not specific objective diagnostic methods and their detection are subjective, such as motion sickness, migraine, irritable bowel syndrome and etc, and 3) flying device factors(ergonomics and exhaustion), operational and airbase factors(work and rest schedule), Personal factors(life style, physical and psychological capabilities, socioeconomic state, use of legal and illicit drugs and habits), medical factors(medical and psychological advices and hygiene education) are important items which have effective influence on cadets health.

The present study has important benefits such as: 1) at yet, this is the first study on EPMD of military cadets in the world, 2) it has the longest cross-sectional period (35 years) that other longest studies has a period of 10 years, and 3) data presentation in order to kills of cadets and aviation trainees.

At the end, we are suggested that, while it is necessary to conduct similar studies in military and civil cadets and pilots (ever-in non-pilots' flight crew), this advises were recommended to prevent the recurrent medical dispensation of military cadets:

1) Facilitate the comprehensive electronic system for record military cadets' medical profile
2) Upgrading of on-the-job examinations of cadets based on the real requirements
3) Sufficient periodic in-service examination of cadets
4) Lifestyle modifications (habits, nutrition, smoking, use and abuse of drugs and substances, physical exercise etc)
5) Use of medical and psychological counseling (motivation, stress management, high-risk behaviors, risk aversion)
6) Hygiene and health education
7) Regular fitness-based training
8) Updating of flying systems, operational devices and air base facilities (ergonomics, work and rest schedule)
9) Effective and powerful preventive systems with regular updating
10) Improvement of services, which provide with occupational health centers.

Declarations

Ethics approval and consent to participate:
The ethical approval of this study was issued with registration N# 1016794 by the Ethics Committee of the Aerospace and diving medical faculty.

Consent for publication:
I (Dr HamzeShahali as Corresponding Author), on behalf of the authors, expresses my satisfaction with the publication of this study in that valuable journal.

Availability of data and materials:
All the data of this study is available and could be accessible for publication by that valuable journal.

Competing interests:
I declare that there is no competing interest about the authors of this study, at all.

Funding:
This research was my special doctorate thesis and so, all the expenses were paid personally. I declare that I did not use any government funds to conduct this study, at all.

Authors' contributions:
Title Presentation, basic researching, approval the research subject, obtaining the necessary permits, collecting data and writing the paper was conducted by Dr HamzeShahali as Corresponding Author and Data analysis, editing and writing part of the article was done by Dr AzadeAmirabadi Farahani as Co-Author, too.

Acknowledgements:
I would like to thank from all the staff of the IRIAF Center for Aviation Physiology and all my colleagues in aerospace and diving medical faculty. I dedicate this study to my spirit Master professor Dr Jalali.

Developing a conceptual model for healthcare services branding in the military hospital

Hamid R. Rasouli[1], Amir H. Tadayon[2], Mohammad R. Mashayekhi[2], Mohsen A. Farajzadeh[2]

Abstract: *Introduction: Given fast grow and competition in the healthcare industry, managers and health activists in this sector need to adopt strategies for branding. The purpose of the study was to develop a conceptual model for branding in the healthcare industry to build brand advocacy and positive brand image.*

Methods: The study includes patients referred to a military hospital in May 2018. Data gathered by questionnaire, and 162 surveys were collected by simple random sampling method. To test the hypotheses, the conceptual model was analysed by structural equation modeling with SmartPLS® software.

Results: The affective commitment and brand trust could predict brand advocacy. CSR significantly impacts brand image and affective commitment, furthermore brand attitude and COB significantly impact brand trust. There was no significant relationship between brand trust and affective commitment with brand image.

Conclusion Organizations can improve brand image and establish brand support through investing resources on branding. This study contributes insights for marketing managers in developing successful branding strategies for health care organizations.

Keywords: *branding, health care industry, hospitals, SEM*

INTRODUCTION

Healthcare services are dynamic, competitive and full of turbulence. The number of hospitals and healthcare providers rising continuously and with this situation, the atmosphere becomes more and more competitive. Furthermore, in Iran, hospitals can't advertise themselves (It's a law) for gaining more patients and customers (Maleki, 2016). In the other view, measuring the efficiency of healthcare services is depending on lots of quantitative and qualitative criteria (like capable employees, behavioural and technical interactions, treatment matter, type of patient, public and private services) and because of that, it is hard to measure (Thantry et al., 2006).

Due to the hard situation for hardware and material distinction, organizations prefer to be distinct in software (Kotler & Keller, 2012). Huge different exists between services and product usage and because of that, considering people who use them, is different and need other conceptualization (Wang et al., 2009; Van Riel et al., 2001). Moreover, a brand in the service sector corresponds with "organization" whereas in the production sector correspond with "product" and according to this, conceptualizing in the service sector is essential (Wang et al., 2009; Chahal & Bala, 2012). When a high value of satisfaction and emotional commitment is issue, branding in hospitals that refer to customer needs is crucial (Kemp et al., 2014).

Corresponding author: Mohsen Abbasi Farajzadeh

[2] Marine Medicine Research Center, Baqiyatallah University of Medical Sciences, Tehran, Iran

Health care is one of the most critical services that a patient receives (Kemp et al., 2014). Like brand in product sector that has socio-psychological attributes, for service sector, brand is same and can be inspiring. This means there is a bond between brand and customers (Kemp et al.). The relationship between brand and customer is binary. Developing relationships between brand and customer can be a challenging procedure and in a different pattern. For example, it is possible that nexus among brand and customer is according to simple or emotional cognition (Park et al., 2009; Thomson et al., 2005; Brakus et al., 2009; Grisaffe & Nguyen, 2011). When there is a strong relationship between brand and customer, the organization has a significant advantage in competitive atmosphere and also can immune organization from rivals (Kemp et al.).

The progress of healthcare services and economic development are closely linked; reaching one without other is impossible (Khodadad & Behboudi, 2017). Branding in healthcare services is a newfound phenomenon, but managers are gaining intuition from its competitive advantage. Meanwhile, hospitals as an expensive part of the healthcare industry that assign a high portion of GDP, need more attention and considering (Nasiripour et al., 2010). Branding plays a vital role in service organizations through increasing customer trust, make a better condition to illustrate services, acts as a mean of competitive advantage and gives value to the customers (Chahal & Bala, 2012). Branding in healthcare services requires a strong and organized commitment to presenting unique services. For having successful branding, managers should have a strategy for maintaining and guiding values for making trust and also managing emotion (Kemp et al., 2014; Mangini, 2002).

The purpose of the study was to develop a conceptual model for branding in the healthcare industry to build brand advocacy and positive brand image.

METHODS

This descriptive study surveyed patients who went to a military hospital in 2018 may, using simple random sampling. To determine the minimum sample size before gathering data Kock and Hadaya (2018) suggest the use of the inverse square root method, which estimates 160 samples. After distributing the questionnaires, 162 samples were gathered. The questionnaire that distributed had two parts, first demographic questions and then 28 questions that evaluate survey variables in Likert-5 scale. The research constructs were developed based on prevalidated measures (Table 1). Instrument items were modified by experts in any aspects and rephrased.

Table 1: Validity and reliability

Construct	Cronbach Alpha (α)	Composite Reliability (CR)	Average Variance Extracted (AVE)	Source
Corporate Social Responsibility	0.856	0.920	0.700	Kemp et al, (7)

Customer-oriented Behavior	0.9	0.929	0.768	Kemp et al, (7)
Affective Commitment	0.883	0.936	0.831	Kemp et al, (7)
Brand Trust	0.890	0.932	0.821	Kemp et al, (7)
Brand Image	0.809	0.872	0.583	Wu (67)
Brand Advocacy	0.739	0.869	0.623	Kemp et al, (7)

After data gathering, single variable and two variables measurement analyses with SPSS® version 25 software and analysis in structural equation modeling calculated with Smart-PLS® version 3.2.7 (Ringle et al., 2015). Cronbach alpha (recommended threshold ≥ .7) (Cronbach, 1951) and composite reliability (CR) (recommended threshold ≥ .7) (Hair et al., 2016) estimated for reliability and average variances extracted (AVE) (recommended threshold ≥ .5) (Fornell&Larcker, 1981) estimated for validity with Smart-PLS®. Results of Validity and Reliability analysis (Table 1) exemplified acceptable value as exceeded recommended threshold, which is an indication of a validated and reliable instrument.

RESULTS

Researchers can figure out data essence with descriptive results. Results of descriptive analysis like gender, age, education, insurance and hospital familiarity (or use duration) are in Table 2.

Table 2: Demographic statistics

Measure		Frequency	Percentage
Gender	Male	94	53.4
	Female	82	46.6
Age	Under 20	8	4.5
	21-30	54	30.7
	31-40	47	26.7
	41-50	33	18.8
	Above 50	34	19.3
Education	Under diploma	40	22.7
	Diploma	50	28.4
	Bachelor	56	31.8
	Master	24	13.6
	Doctoral	6	3.4
Having Insurance	Yes	170	96.6
	No	6	3.4
Time of being hospital customer or (familiarity)	Under 1 year	78	44.3
	1 year	30	17
	2 years	21	11.9
	3 years	10	5.7
	Above 3 years	37	21

Most participants were male (53.4%), 30.7% were 21-30 years old, 31.8% had bachelor degree, almost every participant has insurance (96.6%), and 44.3% of participants were being hospital customer under one year. Constructs averages and standard deviations are in Table 3.

Table 3: Average and Standard Deviation of research constructs

Construct	Average	Standard Deviation
Corporate Social Responsibility (CSR)	3.806	0.971
Brand Attitude (BA)	4.117	0.514
Customer-oriented Behavior (COB)	3.458	1.239
Affective Commitment (AF)	3.448	1.266
Brand Trust (BT)	4.152	1.06
Brand Image (BI)	4.190	0.793
Brand Advocacy (BA)	4.024	0.743

In two variable analyses, researchers used Spearman coefficient correlation. Results of this analysis are in Table 4.

Results of assessing hypotheses using structural model in smart-PLS® (Ringle et al., 2015) (standard and T-values, values in parenthesis in the model) are in Figure 1 which shows H1a, H1b, H2a, H2b, H3 and H4 confirmed and H2c, H5 and H6 rejected. Results are in Table 5.

Table 6: Model assessment results

Construct	Average
Affective Commitment	0.446
Brand Trust	0.346
Brand Image	0.657
Brand Advocacy	0.553

Finally, according to Tenenhaus, the goodness of fit measured and according to formula

$$\mathrm{GOF} = \sqrt{\mathrm{Communality} \times \mathrm{R}^2} = 0.492$$

calculated that exhibits well goodness of fit (Tenenhaus et al., 2004).

DISCUSSIONS AND CONCLUSIONS

This research aimed to find a pattern for branding in the healthcare industry. Hence, variables like corporate social responsibility, brand attitude, customer-oriented behavior, affective commitment, brand trust, brand image, and brand advocacy recognized and the relationship between them through a conceptual model is investigated. Results showed corporate social responsibility has a significant effect on emotional commitment and brand image; these results are in accordance with recent researches (Kemp et al., 2014; Alrubaiee et al., 2017; Kolade&Ogunnaike, 2014). Brand image mostly previses corporate social responsibility. Therefore, by developing corporate social responsibility, brand image become better in customer mind, and marketing performance will improve. Besides, managers can determine policies and strategies in marketing more efficient due to this results and structures. Furthermore, it is crucial for hospitals to invest and help society, which can create an emotional bond and affective commitment.

According to the results, brand attitude and customer-oriented behavior predicted brand trust, and this is following Kemp et al. research (Kemp et al., 2014). Thus, creating a positive brand attitude and customer-oriented behavior from employees will improve brand trust. Educating employees for having better conduct and behavior with customers can improve customer-oriented behavior. Since the healthcare industry is a personal service and a close relationship exist between parties, trust is crucial due to personal information, mental and physical status exposure to healthcare providers (Kemp et al.).

Brand trust could not predict affective commitment that is in the opposite of previous surveys (Kemp et al., 2014; Patawayati et al., 2013; Feiz et al., 2016). However, it could predict brand support that is in accordance with previous researches (Kemp et al.; Moreira & Silva, 2015; Ansari &Mohammadi, 2016). Results showed with brand trust rise up; brand support will rise simultaneously. Hospitals should focus on high trust level in marketing (Kim et al., 2004). When a customer trust in healthcare service provider, it is possible that he/she continues to use that service provider and suggests it to others. Hospitals should use their sources to invest in developing more trust for creating more brand advocacy. Results showed affective commitment could predict brand advocacy and it is in accordance with previous surveys (Kemp et al.; Moreira & Silva; Feiz et al., Ansari &Mohammadi), so by developing an emotional relationship with customer, he/she becomes a brand advocator and finally, competitive advantage will be created.

This research demonstrates the advantages of branding and establishing a meaningful relationship with customers. Results of this research can help marketing managers and strategic planners. In the healthcare industry, vicinity with a hospital is a key factor for productivity (Beckham, 2000). Nevertheless, with increasing healthcare costs and more options for customers, marketers can act more strategic through creating competitive advantage, and distinguishing customers' needs (Brakus et al., 2009).

Healthcare organizations should effectively put their organization and its brand as a valuable factor in providing unique services. As proposed in this research, corporate social responsibility, affective commitment, customer-oriented behavior, customer engagement (like customer relationship management) and trust, are significant elements to reach this goal.

Although this study can help in creating and developing brands in healthcare services, future research and surveys in this field are imperative. Several limitations have existed in this study. First, as data gathered in a cross-sectional way, no cause and effect relationship can be established about research variables. Investing in a relationship between latent variables through longitudinal data is suggested. Future studies can investigate how the correlation between performance and actual satisfaction can create a connection between brands and consumers. Second, some discordance observed between the results of this research and literature, so the research results should expand cautiously. Third, respondents to questionnaires are from the same region so, gathering data from diverse regions is suggested. Forth, in this study, healthcare providers were limited to hospitals, more scopes like pharmacy, clinics, medical imaging, laboratories, and dental services should be investigated. Finally, respondents may somehow were not in their best physical and mental condition, so this maybe affects the data gathering and analysis.

At least once in a lifetime, people use healthcare services, and because of that, good experience and relationship with providers are crucial. As changing perspective in healthcare services in future years, research opportunity in strategical branding and marketing fields will be plentiful for healthcare service providers.

Conclusion Organizations can improve brand image and establish brand support through investing resources on branding. This study contributes insights for marketing managers in developing successful branding strategies for health care organizations.

Development of quantitative real-time RT-PCR assay for detection and viral load determination of Crimean-Congo Hemorrhagic Fever (CCHF) virus

Mojtaba Sharti[1], Mohammad S. Hashemzadeh[1], Ruhollah Dorostkar[1]

Abstract: *Background and Aim: The CCHF (Crimean-Congo hemorrhagic fever) virus causes a severe disease in human with a case fatality rate of up to 50%. Since, there is no specific treatment or approved vaccine against CCHF viral infections, an accurate and early detection as well as a reliable surveillance and quantitative determination of viral load is necessary for patient improvement and case management. In this research, our aim was to develop a probe based one-step real-time reverse-transcription polymerase chain reaction (rRT-PCR) assay for in-house quantitative detection of CCHF virus.*

Methods: At first, the highly conserved S-fragment sequence of CCHF virus genome was adapted from GenBank and the specific probe and primers targeting this region were designed. Then, viral RNAs were extracted from 37 blood samples of different patients from east of Iran (Zahedan). The specificity and sensitivity of the probe and primers were also evaluated in positive blood samples, confirmed to have CCHF virus. A standard (PTG19-T vector containing S-fragment) for quantization was also constructed and the viral load was determined in some of positive samples.

Results: From a total of 37 suspicious blood samples, 15 samples were confirmed to be positive for CCHF virus by this probe based one-step rRT-PCR assay and no false-positive result was detected according to sequencing data. The predicted fragment of 176 bp was also confirmed in all positive samples by gel-based electrophoresis analysis. The assay was linear between 10 to 103 copy numbers per each microliter of extracted plasmid for this technique and the viral load determined in one of patient blood samples was 55,000 viral particles per each milliliter, for example. Bioinformatics and experimental evaluations approved the specificity of this assay. The LOD of the assay was 10 (or fewer) copy numbers of viral genome per each microliter of the extracted genome.

Conclusions: This research showed that the developed probe based one-step rRT-PCR assay is a specific, rapid, sensitive and the simple tool for detection and viral load determination of the CCHF virus.

INTRODUCTION

The CCHF (Crimean-Congo hemorrhagic fever) is a widespread disease caused by Nairovirus (a tick-borne virus) of the Bunyaviridae family. The CCHF virus causes a severe disease (a zoonotic viral hemorrhagic fever) in human and is endemic in Africa, the Balkans, Asia, and Europe [1-6]. In Iran, this virus has also caused serious challenges in the Sistan-va-Baluchestan province [7-15]. The fatality rate is about 10-50% [16, 17]. Since, there is no specific treatment or approved vaccine against CCHF viral infections, an accurate and early detection as well as a reliable surveillance and quantitative determination of viral load is necessary for case management, patient improvement, and protection of medical staffs.

Several different laboratory assays can be used for CCHFV diagnosis, including enzyme-linked immune sorbent assay (ELISA), serum neutralization, antigen detection, virus

isolation by cell culture and reverse-transcriptase polymerase chain reaction (RT-PCR) assay [4, 18-21]. CCHFV RNA from different clinical samples is a proper diagnosis target during the acute phase of the infection or even before the beginning of disease when detection of antibody is untrustable or impossible [22-24].

Unlike the traditional two-step RT-PCR technique, the one-step real-time RT-PCR (rRT-PCR) assay does not need to pre-PCR (post-RT) sample handling, avoiding the PCR product dependent probable contamination transmission and resulting in more sensitive, rapid and also higher efficient assays. On the other hand, the probe based rRT-PCR assays have a very high specificity in addition to the mentioned features. Therefore, it has become an accepted recognition method for detecting many microbes [25]. However, in this research we developed a quantitative probe based one-step rRT-PCR assay for detection and viral load determination of the CCHF virus in suspected blood samples of the Sistan-va-Baluchestan prov¬ince of Iran. The aim of this experimental study was to develop a probe based one-step rRT-PCR assay for in-house quantitative detection of the CCHF virus.

METHODS

Collection of sample

To perform this study, we provided 37 blood samples of different CCHF suspicious patients from the Zahedan city in the southeast of Iran. A few samples had already been confirmed to be positive for CCHF viral RNA existence by rRT-PCR analysis (Pasteur Institute, Tehran, Iran) that were also used as the positive control and they had been stored at -70°C.

Extraction of viral genome

Viral genomes were extracted from 0.2 ml of blood samples using the High Pure Viral RNA Kit (Roche-Germany) in 30 minutes, according to manufacturer's instructions. Then, each one of the extracted genomes were dissolved in 50 µl of RNase free water and stored at -70°C until rRT-PCR analysis (of which only 5 µl was required in each assay). It is noteworthy that all of manipulations were performed in a biological hood with class II biosafety.

Designing and synthesizing the specific probe and primers

The nucleotide sequence of S-region of the available CCHFV strains was adapted from the NCBI database (GenBank) and the highly conserved sequences in this region were determinated and specified from the alignment data analysis obtained from MEGA 7 software. Then the specific probe and primers targeting this region were designed using the Oligo software, version 7.0 (Molecular Biology Insights, Cascade, CO, USA) and GeneRunner (Hastings Software, Hastings, NY, USA).

The probe sequence designed for S-region internal sequence was FAM-5'-CAA AAC AGG ATC TAC ATG CAC CCT GCC-3'-BHQ as well as the forward and reverse oligonucleotide primers for S-region internal sequence were 5'-TGG GGK AAG AAR CTY TAT GAG CT-3' and 5'-ATG GAC TTG GTR TGY CCA GAT CC-3', respectively. K, R and Y are the wobble bases. Eventually, the probe and primers were synthesized by the Bioneer Company (Korea).

One-step real-time RT-PCR assay

The probe based one-step rRT-PCR assays were developed by use of QuantiTect® Probe RT-PCR Kit (Qiagen, Hilden, Germany) using both the Applied Biosystem (ABI) 7500 (USA) and Corbet (Rotor-Gene) 6000 (Germany) real-time PCR instruments. The amplification process was performed in 60 minutes within 20 µl reaction mixtures including 5 µl of the viral RNA template, 1 µl (10 pmol) of both primers (0.5 µM in the reaction) and 0.5 µl of the probe (0.25 µM in the reaction). The conditions of real-time cycler were as follows: two single steps of 30 minutes at 50°C (required for reverse transcriptase activity) and 15 minutes at 95°C (required for HotStarTaq DNA polymerase activation); followed by 50 cycles of 15 seconds at 94°C; and 60 seconds at 60°C (collecting the fluorescence data was accomplished at the end of each 60°C step). So, the real-time PCR products were detected trough an increase in the fluorescence intensity from cycle to cycle. Cycling curves were evaluated with respect to negative and positive controls (as the quality controls of the process) in the real-time analysis. The rRT-PCR products were then approved by gel-based electrophoresis.

Evaluation of sensitivity and specificity of the assay

Analytical sensitivity

To determine the LoD (limit of detection) of the assay, serial dilutions containing 1, 10, 100 and 1000 copies of the positive control sample (plasmid) per each microliter of the extracted sample were analyzed. The highest dilution of sample at which 100% of rRT-PCR replicates were positive was considered as the LoD of the assay. In this assay, the LOD was 10 or fewer copy numbers of viral genome per each microliter of the extracted genome (2500 or fewer copy numbers of viral genome per each milliliter of patient blood sample).

Analytical specificity via in silico prediction and rRT-PCR assy

As previously mentioned, none of the probe and primer sequences demonstrated genomic cross-reactivity with other viruses, human genome and other likely interfering genomes in a BLAST search analysis and only detected a 176 bp fragment of the CCHFV S-region in bioinformatics analysis (data not shown). On the other hand, in the experimental rRT-PCR assay, some of the accessible RNA viruses such as norovirus, flu A, HCV, WNV and CCHF (as the positive control) were also evaluated in terms of specificity of the assay.

Linearity range and repeatability of the assay

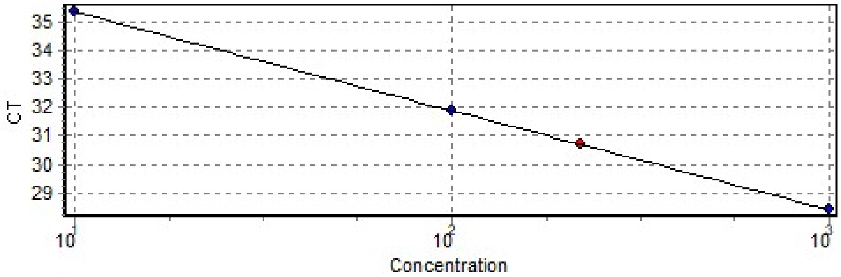
Linearity of the assay was evaluated by analysis of serial dilutions containing 10 to 105 copy numbers of positive control sample per each microliter of extracted plasmid and the assay was linear between 10 to 103 copy numbers per each microliter of extracted plasmid for this technique (Figure 1 – *Ct was plotted against the quantity of plasmid DNA (common logarithmic scale). Measurement of the copy number of CCHF virus was estimated from Ct by quantitative rRT-PCR< 🟥 [in Ct = 30.69] represents unknown patient sample and ■ [in Cts = 35.36, 31.87 and 28.42] represents the standard dilution*). These assays were evaluated and repeated by at least three different users and three times by each one of them on different days and the repeatability of the assays was approved. Also the assays were developed using both the Applied Biosystem (ABI) 7500 (USA) and Corbet (Rotor-Gene) 6000 (Germany) real-time PCR instruments.

Quantitative determination of viral load in positive samples

Construction of a standard for quantization: The fragment of 176 bp within the S-region sequence of CCHF virus genome was amplified by rRT-PCR and the amplicon was cloned into the PTG19-T vector using a T/A cloning Kit (Vivantis, Malaysia). The plasmid was then purified using a plasmid purification kit (Qiagen, Hilden, Germany). After the performance confirmation of cloning process by PCR, the accuracy of this process and the sequence of cloned fragment was confirmed by sequencing. Determination of recombinant plasmid concentration was then performed by a NanoDrop.

For preparation of a standard curve, the plasmid was diluted serially from 103 to 10 copy numbers per microliter as a master of standard positive control. As soon as optimizing the assay conditions, we obtained a standard curve with a linear range across at least three logs of DNA (recombinant plasmid) concentration, from which the Ct values can be referred to the virus copy number (Figure 1).

Figure 1. The standard curve with a linear range across three logs of different concentrations of the recombinant plasmid DNA containing the S-region sequence of CCHFV genome.



Determination of the Ct values and construction of the standard curve were performed using the Rotor-Gene 6000 software. In all real-time PCR assays, the correlation coefficient of the standard curve was greater than 0.980. Ct was plotted against the quantity of plasmid DNA (common logarithmic scale).

Measurement of the copy number of CCHF virus in unknown blood samples from different patients was estimated from Ct by quantitative rRT-PCR. Since, the viral genome was extracted from 200 µl of a patient blood sample, on the other hand, the extracted genome was dissolved in 50 µl of RNase-free water, as well as, 5 µl was only used in each quantitative assay, the final viral load in 1 ml of blood sample would be 50 folds.

RESULTS

Diagnostic assay of CCHF viral RNA in suspicious blood samples

From a total of 37 suspicious blood samples, 15 cases were approved to be positive and 22 were negative for CCHF viral RNA by use of this technique and no false positive was detected in the results of sequencing. The predicted length of 176 bp resulted by rRT-PCR amplification was approved in all the positive samples by electrophoresis analysis (Figure 2A). The amplification curve related to some of the suspicious blood samples evaluated is shown in Figure 2B.

Evaluation of analytical sensitivity of the assay

The serial dilutions prepared containing 1, 10, 100 and 1000 copies of the positive control sample (plasmid) per each microliter of the extracted genome were analyzed in rRT-PCR for the analytical sensitivity evaluation of the assay. As shown in table 1, the highest dilution at which 100% of rRT-PCR assays were positive (underlined) is considered as the LOD, which in this assay was 10 (or fewer) copy numbers of viral genome per each microliter of the extracted genome or 2500 (or fewer) viral particles per each milliliter of patient blood sample.

Figure 2. A) The predicted fragment with the length of 176 bp, resulted by rRT-PCR amplification. Lad is a 50 bp DNA Ladder (SinaClon, Iran).

Evaluation of analytical specificity via in silico prediction and rRT-PCR assay

As shown in Figures 3A and 3B, the highly conserved sequences (yellow) in the S-region were determinated from the alignment data analysis obtained from the MEGA 7 software which were quite specific for CCHF virus, as previously mentioned and the specific primers targeting this region were designed using the mentioned softwares (bioinformatics data for the probe is not shown).

The results of experimental rRT-PCR assay on the accessible RNA viruses such as Norovirus, Flu A, HCV, WNV and CCHFV (as the positive control) showed that this assay was quite specific for CCHFV and other viruses were not detected by the designed probe and primers (Figure 4 - ■ represents NTC [Not template control] or negative control sample, 🟥 [in Ct = 21.44] represents the positive control [CCHFV] sample, 🟦 represents the negative result from Norovirus sample assay, ■ represents the negative result from Flu A sample assay, ■ represents the negative result from HCV sample assay and 🟥 represents the negative result from WNV sample assay).

Figure 4. The rRT-PCR amplification curve related to some of the accessible RNA virus samples

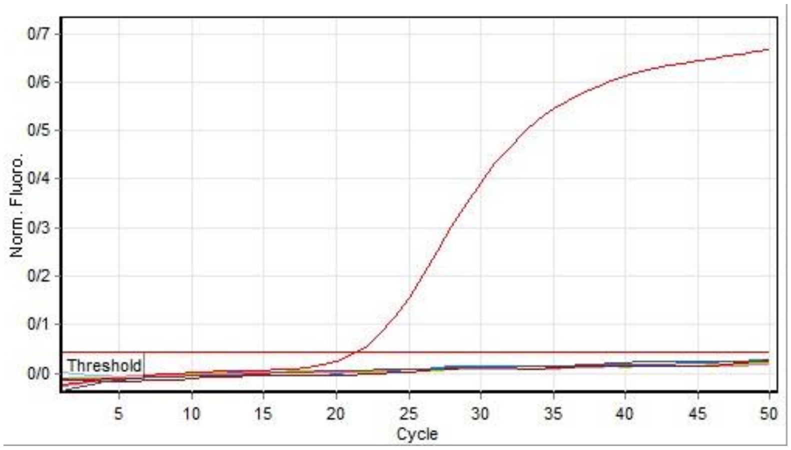

Figure 5. Representative amplification plot of the developed CCHFV quantitative rRT-PCR assay (quantitative curve) showing three ten-fold dilutions of the standards (Cts = 35.36, 31.87 and 28.42) and one unknown sample (Ct = 30.69).

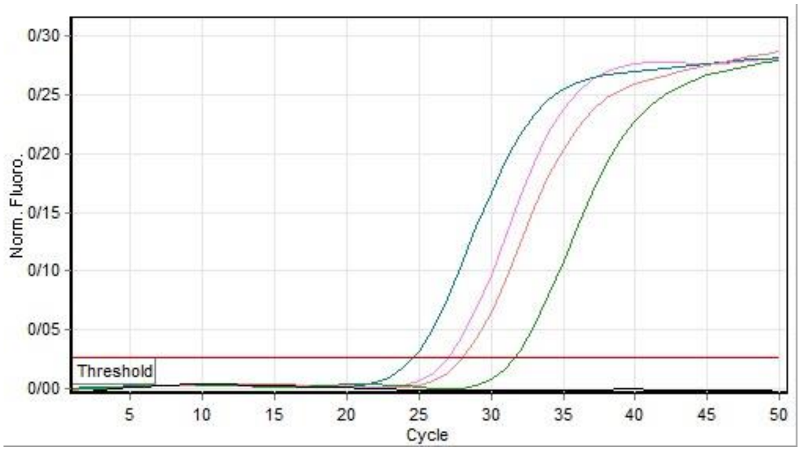

Quantitative determination of viral load in positive samples

The copy number of CCHF virus in different patient blood samples was estimated from Ct by the rRT-PCR assay (Table 2), based on the quantitative curve (Figure 5). For example, the viral load determined in patient blood sample-1 was 220 copy numbers of viral genome per each microliter of the extracted genome or 55,000 (250 folds) viral particles per each milliliter of patient blood sample.

It is notable that viral load decreased slowly in most of cases in subsequent samplings (severe form of disease) and in others (moderate form of disease) decreased very faster. The results of subsequent evaluations is not reported in this article.

Table 2. The calculated viral load of CCHF virus in several patient blood samples based on the quantitative curve and Ct, NTC is "not template control" or "negative control" sample

DISCUSSION

The CCHF (Crimean-Congo hemorrhagic fever) is an acute widespread zoonotic illness, caused by Nairovirus (a tick-borne virus), which is characterized by a severe and often hemorrhagic course of disease, with a fatality rate of about 10-50% [16, 17].

The CCHF viral RNA from various clinical samples is a proper tracing target during the acute phase of the infection, or even before the beginning of the disease when detection of antibody is impossible or unreliable [22-24]. As there is no specific treatment or approved vaccine against CCHF virus, an accurate and early detection as well as a reliable surveillance and quantitative determination of viral load is necessary for case management, patient improvement, and protection of medical staffs.

Several different laboratory assays can be used for CCHFV diagnosis, including enzyme-linked immune sorbent assay (ELISA), serum neutralization, antigen detection, virus isolation by cell culture and reverse-transcriptase polymerase chain reaction (RT-PCR) assay [4, 18-21]. RT-PCR is the best molecular diagnostic techniques in clinical laboratories owing to its simplicity, high specificity and sensitivity [24]. Unlike the traditional two-step RT-PCR technique, the one-step real-time RT-PCR (rRT-PCR) assay does not need to pre-PCR (post-RT) sample handling, avoiding the PCR product dependent probable contamination transmission and resulting in more sensitive, rapid and also higher efficient assays. On the other hand, the probe based rRT-PCR assay has a very high specificity in addition to the mentioned features, compared with the SYBR Green based rRT-PCR assay that was also developed in our previous study [22]. Therefore, it has become an accepted diagnosis method for detecting many microbes [25] and also has greater repeatability when the need for post-amplification processing (analysis by agarose gel electrophoresis) is eliminated, thus avoiding the transfer contamination, difficulty and time-consuming [26, 27].

The assay was linear between 10 to 10^3 viral genomes per each microliter of the extracted genome for this technique and the bioinformatics and experimental evaluations approved high specificity of this assay. On the other hand, the LOD of the assay was 10 (or fewer) copy numbers of viral genome per each microliter of the extracted genome. Measurement of the CCHF virus copy number and quantitative determination of viral load in positive samples was estimated from Ct via the rRT-PCR on the basis of the quantitative curve. It is notable that construction of a standard for quantization of this assay is necessary and very difficult, which was devoted a lot of time in this study.

CONCLUSIONS

This research showed that the developed probe based one-step rRT-PCR assay is a specific, reliable, rapid, sensitive, repeatable and simple tool for detection as well as quantitative determination of viral load of the CCHF virus in various suspicious patient samples.

Abstract: *Objective: The goal of this paper is to present the management of cases of deep endometriosis that affects the bladder, the ureters and the kidney.*

Materials and method: In this review we analyzed the sensitivity and specificity of imaging techniques for diagnosing deep infiltrating endometriosis, the optimal surgical technique and the surgical approach.

Results: In patients with pelvic endometriosis in advanced stages the urinary tract is frequently involved. Preoperative work-up of patients with deep infiltrating endometriosis is aimed at evaluating the extension of the lesions in order to assess the complexity of the intervention and to choose the optimal approach.

Conclusions: Laparoscopic and robotic management of these cases are good therapeutic alternatives. Ultrasound, sonovaginography with gel and MRI are useful imaging techniques for evaluating patients with deep infiltrating endometriois. The surgical management of patients with deep infiltrating endometriosis that involves the urinary tract consists of partial bladder resections, ureterolysis, ureteral resection and anastomosis and ureteral reimplantation..

Keywords: *bladder endometriosis, deep infiltrating endometriosis, ureterolysis*

INTRODUCTION

Endometriosis is a benign pathology of the female reproductive tract, characterized by the presence of endometrial glands or stroma outside the uterine cavity [1]. The presence of endometrial tissue at the level of the bladder will be stimulated during the menstrual cycle. In response to the cyclical stimulation of hormones throughout the menstrual cycle, some patients may even present with cyclic hematuria [2,3].

Bladder endometriosis can be defined as "primary" or "secondary". Primary bladder endometriosis is represented by lesions associated with deep infiltrating endometriosis.

Secondary bladder endometriosis is represented by lesions that have occurred iatrogenically after pelvic surgery, caesarean section or hysterectomy [4,5].

The distribution of the lesions is multifocal, affecting the bladder trigone and dome from the serosa to the mucosa [6,7].

The ectopic endometrial tissue is subjected to stimulation during the normal cycle creating hormonal changes that result in

bleeding, inflammation and adhesions [8]. The two main manifestations of this disease are chronic pelvic pain of varying intensity and infertility [9,10].

Table 1: The prevalence of urinary tract endometriosis [11]

Kidney	4 % of all urinary tract locations
Ureter	9 % of all urinary tract locations
Bladder	85 % of all urinary tract locations
Urethra	2 % of all urinary tract locations
Prevalence	0,3 – 12 % of all cases of endometriosis

DIAGNOSIS

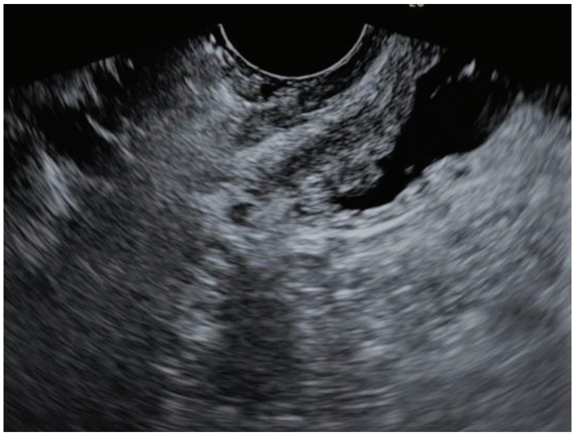
The diagnosis of bladder endometriosis is based on the presence of ectopic endometrial glands and stroma located at the level of the detrusor muscle. Patients presenting with bladder endometriosis often present nonspecific urinary symptoms. In some cases, patients will present with dysuria, urgency to void, frequent micturition and abdominal pain [12,13]. The main aspect that dominates the clinical picture is exacerbation of these symptoms during the menstrual period [14]. Due to the fact that the symptomatology of bladder endometriosisis is nonspecific, many women will not seek medical attention in the first few years. The symptomatology can vary depending on the site and the dimension of the lesion [15]. The various degrees of abdominal or pelvic pain associated with bladder endometriosis will not prompt patients to seek additional work-up for this syndrome [16]. Thus, an average of 6 years will pass from the onset of the symptomatology to the diagnosis of endometriosis [17].

Urinary tract endometriosis can present with a non-specific symptomatology [18-20]. The presence of endometrial tissue at the level of ureteral orifices can produce hydronephrosis, with subsequent renal failure [21,22]. If the ureteral obstruction is acute, the symptoms may mimic a renal colic that requires a form of drainage [23-25].In chronic urinary obstruction, the lumbar pain can be absent and the renal insufficiency could appear like arterial hypertension, due to a bad regulation of blood pressure, thus involving the delay of a right treatment [26-28]. The medical history and accurate identification of the patient’s symptoms can guide the clinician in choosing the correct imaging investigations based on the presenting symptoms.

Imaging diagnosis

Ultrasonography is the first line imaging investigation used in the work-up for patients with endometriosis. The bladder and the kidneys can be evaluated using transvaginal and abdominal ultrasound. The patient’s bladder should be in semirepletion for a correct evaluation. (Figure 1)

Figure 1: Vesical endometriosis



Abdominal ultrasound can be used in cases of suspected lesions of the bladder, abdominal wall and umbilical endometriosis [29]. During the initial work-up of a patient with deep infiltrating endometriois, an abdominal ultrasound must be performed to evaluate the impact on the ureters and kidneys. Endometriotic lesions can affect the ureter extrinsically or intrinsically. This can have an impact on the kidney causing hydronephrosis or ureterohydronephrosis. Any other causes of ureteral extrinsec compression must be excluded [30-33]. If surgical excision of the lesions is not performed this may affect the kidney leading to loss of function [19-25].

There are some authors that suggest that ureteral endometriosis should be suspected in all cases of deep infiltrating endometriosis [34].

Sonovaginography with ultrasound gel is a useful diagnostic option in cases with deep infiltrating endometriosis. This method is useful for identifying endometriotic lesions in the posterior compartiment as well as in the anterior compartment. An acoustic window is created by introducing 20 ml of ultrasound gel into the vagina. The technique initially used saline solution [35]. Using this technique, we observed a high diagnostic accuracy for the following locations (transvaginal ultrasound – TVS sonovaginography with gel – SVG) – Table 2.

Table 2. The diagnostic accuracy for transvaginal ultrasound and sonovaginography with gel in the anterior and posterior compartiment [36].

Endometriotic lesion	Ultrasound	Sensitivity	Specificity	PPV	NPV
Ovaries	TVS	94.8 %	95.6 %	92.5 %	94 %
	SVG	95.5 %	97 %	92.6 %	93 %
Urinary bladder	TVS	65.5 %	98.6 %	66.6 %	98.5 %
	SVG	67 %	97 %	98 %	98 %
Utero-sacral ligaments	TVS	69.7 %	95 %	84.2 %	87 %
	SVG	78.5 %	96 %	89 %	91 %
Vagina	TVS	58.5 %	99 %	94.3 %	95.4 %
	SVG	79 %	99 %	92 %	96 %
Recto-vaginal septum	TVS	64.8 %	99.4 %	81.5 %	97.8 %
	SVG	94 %	97 %	82 %	93.5 %
Pouch of Douglas	TVS	81.5 %	99 %	95 %	97 %
	SVG	81 %	98 %	91 %	97 %
Recto-sigmoid	TVS	91 %	97 %	95 %	96 %
	SVG	94 %	95.5 %	91 %	97.2 %

In the anterior compartment the transvaginal ultrasound and sonovaginography with gel have a similar sensitivity and specificity (80.1 % vs 81.2 % and 97.1% vs 97%). However, the positive predictive value is in favour of the latter (79.5 % vs 95.3 %). In cases of with deep infiltrating endometriosis the association between magnetic resonance imaging and computer tomography- based virtual colonoscopy has a sensitivity of 98.36 % for nodule identification. The association of these two investigations allows a superior mapping of the endometriotic lesions at the level of the posterior compartment. This aspect is important in the preoperative work-up and planning for the surgery [37].

TREATMENT

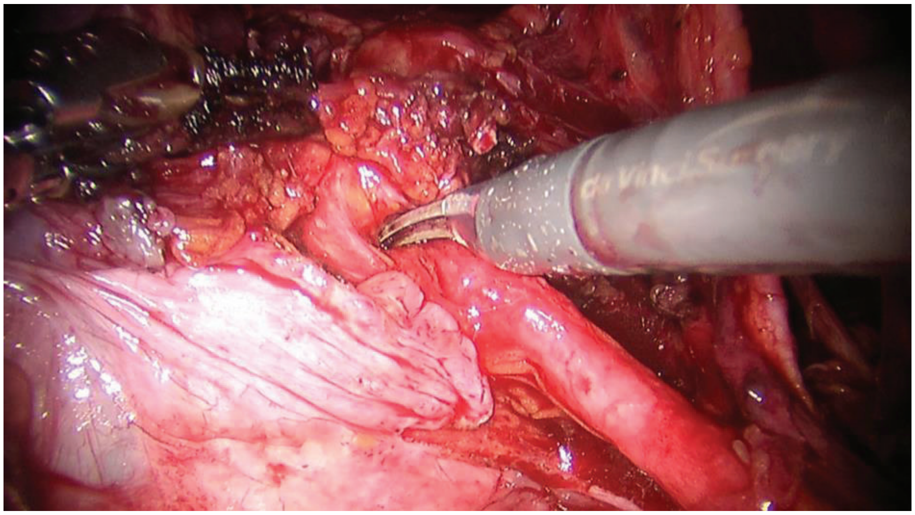
Medical treatment

Medical treatment using progestins, oral contraceptives and GnRH agonists can be used in the treatment of patients with endometriosis [38-40]. The contraindications of medical treatment in patients with urinary tract endometriosis are: evidence of the kidney being affected by hydronephrosis, the patient's desire and contraindications for the treatment [41,42]. The imunohistochemical aspects of patients treated with progesterone can be useful in choosing the optimal medical treatment after the surgical intervention [43,44]. The expression of the anti-apoptotic markers (Bcl-2), cell proliferation markers (Ki-67), estrogen and progesterone receptors offers anexplanation for the different outcomes after medical treatment for patients with endometriosis [45,46].

Surgical treatment

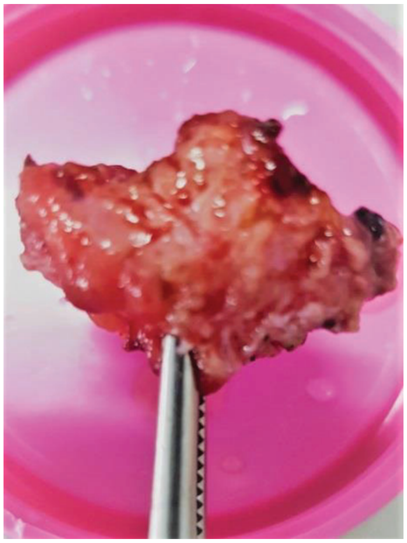
Surgical treatment of urinary tract endometriosis must be performed when the patient does not respond to medical treatment, if the patient suffers from infertility or if the lesion has an impact on the kidney (ureteral obstruction, hydronephrosis or uretero-hydronephrosis) [47,48]. Due to the fact that the obstruction of the ureter is due to fibrosis, patients will not respond well to medical treatment [49,50]. During the initial work-up and planning for the surgical intervention, the symptoms exhibited by the patient and the imaging investigations can guide the therapeutic conduct and anticipate the complexity of the case [51,52]. This is a key aspect in deciding the optimal intervention for the patient and anticipate whether a multidisciplinary approach is in order (gynaecologist, urologist and colorectal surgeon) [53,54]. The treatment for bladder endometriosis is represented by the surgical excision of the lesion.

Figure 2: Robotic ureterolysis (*Personal collection of Prof. Elvira Brătilă*)



The surgical approach can be performed by laparotomy, laparoscopy or robotic surgery (Figure 2) [55-57]. The treatment for ureteral endometriosis consists of the surgical excision of the lesions involving the ureters in order to prevent ureteral compression (Figure 3).

Figure 3: Endometriotic lesion of that affected the ureter extrinsically at the level of the vesicoureteral junction (*Personal collection of Prof. Elvira Brătilă*)



Ureterolysis is the first procedure performed when the lesion affecting the ureter is extrinsic. During the laparoscopic and robotic surgery, the transperitoneal approach way allows a thorough evaluation of the extension of the disease.

When the ureters are affected intrinsically, the ureteral segment can be infiltrated by the endometriotic lesions. In this case, a resection of the affected segment and reimplantation can be an alternative if ureterolysis cannot be performed [58,59].

After the completion of the ureterolysis (dissection of the tissue up to the level of the cardinal ligament), a thorough assessment of the remaining segment is required [60]. This must take into account the possibility of another obstruction of the ureter. The level at which the ureter is affected represents a factor for the intraoperative decision to perform ureterolysis, ureteral resection and anastomosis or ureteroneocystotomy [61,62]. If the lesion is located in the distal part of the ureter, the affected segment can be resected and the ureter can be reimplanted in the bladder. If the lesion is located in the upper third of the ureter, the affected segment can be resected and repaired with an uretero-ureteral anastomosis. The choice between ureterolysis and resection cannot be made preoperatively.

CONCLUSIONS

In patients with pelvic endometriosis in advanced stages, the urinary tract is frequently involved. Laparoscopic and robotic management of these cases is a good therapeutic alternative [63,64]. Preoperative work-up of patients with deep infiltrating endometriosis is aimed at evaluating the extension of the lesions in order to assess the complexity of the intervention and to choose the optimal approach [65,66]. Ultrasound, sonovaginography with gel and MRI are useful imaging techniques for evaluating patients with deep infiltrating endometriosis [67]. The surgical management of patients with deep infiltrating endometriosis that involve the urinary tract consists of ureterolysis, ureteral resection and anastomosis and ureteral reimplantation [68-70].

Diagnosis of malignant neoplasms of the skin in servicemen of the Armed Forces of Ukraine

Kushnir Valeriy[1], Lysenko Dmytro[2]

Abstract: *Objective: Malignant neoplasms of the skin are diagnosed in high-risk groups, among which the military is special. The article is devoted to the analysis of diagnostics, and risk factors for malignant skin tumors in servicemen of the Armed Forces of Ukraine (AFU)*

Materials and methods: An analysis of 23 cases of diagnosed malignant neoplasms of the skin in servicemen of AFU for the period 1999-2021. The study included cases in which the diagnosis was confirmed histologically in two laboratories. Clinical, laboratory, and histological data of each case were analyzed, and further analysis took into account the length of military service and the risks of professional activity.

Results: Among the 23 cases, the majority - 22 were servicemen, and only 1 case of basal cell carcinoma in a 52-year-old employee. Among other servicemen, the age range was 25-55 years, with a mean age of diagnosis of 42 years. The period of military service at the time of diagnosis was 23.7 years, most cases were melanoma (15 of 23 cases), and in other cases - basal cell carcinoma. Patients were dominated by Air Force personnel (10 out of 23 cases)

Conclusion: The prevalence of malignant skin neoplasms in the Armed Forces corresponds to global trends. A group of increased risk of developing malignant skin neoplasms is servicemen of the Armed Forces of Ukraine with a long service life (more than 20 years), older than 40 years. However, there is a high probability of developing melanoma of the skin in servicemen of shorter service life, which requires enhanced dermatological supervision in servicemen of any age and service life.

Keywords: *malignant neoplasms of the skin, servicemen, armed forces of Ukraine*

INTRODUCTION

Malignant neoplasms of the skin are diagnosed in many age, national and occupational groups, due to numerous risk factors studied in great detail by dermatologists. Among them are insolation, contact with carcinogens, genetic factors, and many others [1]. However, among professional groups, the high-risk group – the military – attracts attention, which clearly demonstrates the acquired nature of the development of skin cancer [2]. After all, as a standard, at enlistment in military service, people with potential risk factors and precancerous diseases are eliminated and development in the future of such new growths is caused by features of professional activity.

It is proved [3] increased risk of malignant neoplasms of the skin and servicemen who had increased contact with ultraviolet radiation, and this trend has been observed over the past 100 years in participants of World War I and II, the Vietnam War, and other armed conflicts of the 20th century [4]. Among the military, two groups are known to have high levels of skin cancer: Caucasians and men over 50 [5]. Among the military, the Air Force has the highest rate of both melanoma and non-melanoma skin cancer [6]. Accordingly, officers, especially senior officers, have an increased incidence of melanoma and non-melanoma skin cancer compared to non-military personnel [7]. The significant role of ultraviolet radiation is indicated by the fact that pilots have the highest risk of developing malignant skin tumors among other groups of servicemen [8]. It is noted that the levels of ultraviolet radiation increase to 24 percent with each increase in altitude by 1000 meters [9]. The publications on the diagnosis and manifestations of malignant skin neoplasms are mainly based on data from the

US or other NATO countries [2-9], we have not found publications on the analysis of diagnosis, risk factors for malignant skin tumors in the Armed Forces of Ukraine (AFU). Based on this, we set a goal – to analyze the features of diagnosis and manifestations of malignant neoplasms of the skin in the Armed Forces.

MATERIALS AND METHODS

We analyzed 23 cases of diagnosed malignant skin neoplasms in the Armed Forces of Ukraine for the period 1999-to 2021.

The data were obtained from the reports of surgeons and dermatologists in the hospitals of the Armed Forces of Ukraine. The study included cases in which the diagnosis was confirmed histologically in two laboratories. Clinical, laboratory, and histological data of each case were analyzed, and further analysis took into account the length of military service and the risks of professional activity. The study did not include suspected cases of malignant neoplasms not confirmed by repeated histological examination.

RESULTS

Among the 23 cases, the majority - 22 were servicemen and only 1 case of basal cell carcinoma in a 52-year-old employee.

Among other servicemen, the age range was 25-55 years, with a mean age of diagnosis of 42 years. There were 13 and 9 officers and sergeants, respectively, and servicemen, which does not allow to define of this indicator as a risk factor. The term of military service turned out to be a more predictable risk factor, as it amounted to 23.7 years, which practically corresponds to the average term of service of a serviceman of the Armed Forces. However, we note the presence of three cases of diagnosis of malignant neoplasms that occurred after 1-3 years of military service. These were cases of solid basal cell carcinoma in a 37-year-old soldier, a case of anonymous melanoma in a 25-year-old soldier, which was detected in the stage of widespread metastasis after 2 years of service, and primary multiple melanomas in a 44-year-old soldier, which was detected in 3 years of service. All these cases required radical treatment and led to dismissal with subsequent disability of patients.

Officers were dominated by skin melanoma in 9 of 13 cases, which was detected after 20 years of service and did not require urgent radical treatment, and in 5 cases did not lead to dismissal.

Further analysis of nosology and its prevalence revealed that most cases were melanoma (15 of 23 cases), in other cases – basal cell carcinoma. Other risk factors were predominantly in the Air Force (10 out of 23 cases), consistent with other studies on the increased risk of developing skin neoplasms in military personnel involved in flight missions and a significant increase in ultraviolet radiation.

DISCUSSION

Due to the prevalence of malignant skin tumors among APU servicemen relative to other population groups, it is difficult to make an adequate comparison. According to our data, the studied population of sick servicemen was in the age range of 25-55 years and mostly male, according to data for 2020 the incidence of melanoma in men was 7.4 per 100 thousand population, and non-melanoma malignancies 38.2 per 100 thousand population [10]. However, no data have been found on age, and it should be borne in mind that servicemen are a group of enhanced surveillance, in which early diagnosis is present and potential risk groups are excluded. In our opinion, it is not correct to compare the civilian population and the military.

In our opinion, it is the consideration of the peculiarities of the factors of supervision and closes medical examination of servicemen that should be taken into account when comparing the data on the incidence of malignant skin neoplasms in this category of the population and other populations. In particular, there are data [2] on the absence of a difference in the incidence of melanoma between the general population of the United States and the US Navy or Air Force, and even on reduced age-adjusted rates compared to civilians [5].

However, there is evidence of an increased risk of melanoma in US servicemen over the age of 45 [4], which is consistent with our data on a significant percentage of patients in this age group. The predominance of Air Force patients among patients is in line with the global trend and indicates the need for more careful supervision in this group of servicemen. Also noteworthy is the presence of a group of patients with relatively short service life in the Armed Forces and young people, who were diagnosed with malignant skin tumors with signs of disease progression, which is not a standard situation in this age group, but described the development of melanoma in 27-year-old US serviceman [11], which indicates the need for close medical examination of young servicemen and short service life.

CONCLUSIONS

The prevalence of malignant skin neoplasms in the Armed Forces corresponds to global trends. A group of increased risk of developing malignant skin neoplasms is servicemen of the Armed Forces of Ukraine with a long service life (more than 20 years), older than 40 years. However, there is a high probability of developing melanoma of the skin in servicemen of shorter service life, which requires enhanced dermatological supervision in servicemen of any age and service life.

Diagnostic challenges in gastrointestinal infections

Nicoleta Negrut[1], Shamim A. Khan[2], Simona Bungau[3], Dana C. Zaha[4], Corb A.R. Anca[4], Ovidiu Bratu[5], Camelia C. Diaconu[6], Florentina Ionita-Radu[7]

Abstract: *Gastrointestinal infections are among the most common infectious diseases found all over the world, varying depending on the etiological agent. Symptoms usually include diarrhea, vomiting, and abdominal pain. Water and electrolyte imbalance is the main consequence of gastrointestinal infections. Most of them are cured or self-limited in few days, but at the same time, for a specific population such as immunocompromised, elderly patients or new-borns, these infections are potentially severe. In this context, it is very important to identify the etiological agents of acute diarrhea for the appropriate treatment and infection control measures. While routine laboratory diagnosis of parasitic diarrhea still depends largely on microscopic examination of fecal samples, immunological and molecular methods are becoming increasingly commercially available and, in well-resourced settings, will ultimately displace traditional methods. The present paper presents some of the most common and well-known pathologies of this type, being a brief presentation of the variety of gastrointestinal diseases, each with characteristic clinical manifestations and diagnosis.*

Keywords: *gastrointestinal infections, Rotavirus, Salmonella, Shigella, Helicobacter pylori*

INTRODUCTION

Worldwide, acute gastrointestinal infections are the second most common infectious diseases after respiratory tract infections and a major cause of morbidity and mortality among infants and children [1]. Gastrointestinal infections can be caused by a large number of microorganisms present in the water, food, or hospital environment, that cause inflammation of different segments of the gastrointestinal tract. The prevalence of the different microorganisms causing gastroenteritis depends on several factors, such as age (children, adults), community or nosocomial acquisition, country (developing or developed), patients who have traveled abroad and immune status [2].

The common clinical picture usually looks like acute gastroenteritis, with a sudden or insidious onset, immediately after or after a while from returning to the country of origin. At the first presentation, it is important to identify the patient's journey, with detailed information on particular aspects of the trip. Failure in identification of the epidemiological link may lead to delayed diagnosis and treatment, with increased risks of complications. Empirical intervention is often important when there is a strong possibility of a certain condition and confirmatory lab tests

are delayed or unavailable, especially for infections that are rapidly progressive or with prolonged testing duration [3].

Traveling for business and pleasure is a small proportion of the total movement of people. Modern transport ways allow more goods and people to travel around the world at a faster pace; they also open up the airways to the transcontinental movement of vectors for infectious diseases. While traveling, people carry their genetic profile, immunological sequelae from previous illnesses, cultural preferences, traditions, and patterns of behavior. They are also accompanied by microbes, animals and other biological lives [4]. The range of infectious diseases present at a certain time and in a certain region has increased, with the increasing travel possibilities from one country to another and between continents. Transiting through different geographical areas, in a short time (as with long-distance flights), may increase the risk of contamination with foreign etiological agents. Cities are becoming important centers for the transmission of infectious diseases due to international travel and migration, as shown by recent pandemics. Several factors contribute to infectious disease emergence. Others commonly listed include microbial adaptation and change, demographics and behaviour, changes in the environment, technology and economic development, deterioration of public health and surveillance programs, and international travel and trade [5].

Many tropical diseases havea polymorphic clinical feature, making the diagnosis difficult, especially for clinicians from countries outside tropical areas. In developing and developed countries, doctors in urban settings need to be aware of developments in infectious diseases. Upon travel, an ill traveler's history must analyze exposure specifics, including visited destinations, activities, ingestion of infected food or drink, contact with insects, livestock, freshwater or blood and body fluids and other possible exposures. Information on the geographic dissemination of infectious disease is significant in creating the differential diagnosis and testing [6].

The purpose of this paper is to make a brief review of the most common gastrointestinal infections, with their relevant clinical features and diagnosis.

GASTROINTESTINAL INFECTIONS

In the geographical area of Romania, southeastern Europe, Rotavirus, Salmonella species, Shigella species, Clostridium difficile, Escherichia coli and Giardia lamblia are the most common etiological agents of gastrointestinal infections [7-9]. Infections with Helicobacter pylori, Campylobacter spp., and other viruses are also frequent. Several tropical infectious diseases, such as amebiasis, malaria, leishmaniasis, dracunculiasis, schistosomiasis, brucellosis, leptospirosis, dengue fever, yellow fever and viral haemorrhagic fever, can have a digestive onset, requiring increased attention from the clinician. Experimental animal studies and clinical research have shown that the virulence of infectious microbial agents can have variable severity, sometimes being involved even in deaths because of sepsis [10, 11].

Viral gastrointestinal infections

The most important etiological viral agents of diarrhea are rotavirus, norovirus, adenovirus, astrovirus, sapovirus and enterovirus. Gastroenteritis caused by norovirus, asingle-stranded RNA (ssRNA) viruses belonging to the family of Caliciviridae, may manifest with severe nausea, vomiting and diarrhea. The genogroup I (GI), II (GII) and IV (GIV) of Rotaviruses (double stranded RNA) are the main cause of diarrhea in children under 5 yo and responsible for the death of around 200,000 children/year. Rotaviruses belong to the Reoviridae family [12]. Major symptoms are usually abdominal pain, vomiting and waterydiarrhea (AWD). Rotaviruses serogroups A, B, and C are responsible for human infections.

Adenoviruses cause respiratory diseases, bladder infections, conjunctivitis. Adenoviruses belong to Adenoviriadae family of double-stranded (dsDNA) viruses. Taking into consideration 51 serotypes of human adenoviruses (classified into six groups, from A to F), gastroenteritis is mainly caused by Adenoviruses serotype 40 and 41.

Astroviruses discovered in 1975 are single-stranded (ssDNA) viruses and belong to the family of Astroviridae; the incidence of these infections is constantly increasing [13]. Clinical signs include vomiting and severe diarrhea, with moderate dehydration. In developed countries, the Astrovirus infection incidence is between 2-9%, affecting mainly children [14]. To date, serotypes 1 - 5 are the most relevant. Serological studies indicate that most children infected with Astroviruses develop antibodies to the virus early in life, which provide protection against future infections.

Sapoviruses are part of the family of Caliciviridae and are major causative agents of gastroenteritis worldwide, causing disease in humans of all ages. The highest incidence was described for children under 5 year-old, but infections are diagnosed in adults as well, with diarrhea, vomiting, and fever (similar clinical symptoms to those of norovirus infections). However, self-limited sapovirus infections lead to less severe gastroenteritis compared to norovirus-induced gastroenteritis [15].

There is a variety of different subtypes of human enteroviruses, such as human enterovirus 70/71, poliovirus, Coxsackie virus A and B, echovirus, with different degrees of tissue tropism and virulence, although retaining a basic antigenic identity. Infections are usually asymptomatic or present with mild cold-like symptoms. Severe enterovirus infections are poliomyelitis, meningitis and myocarditis. Coxsackie viruses are present worldwide and can cause the so-called “summer diarrhoea”. Other severe infections with Coxsackie virus or human enterovirus 70/71 can lead to conjunctivitis and myocarditis, whereas echovirus infections can result in aseptic meningitis, with echovirus 30 being the most common meningitis-causing serotype in Europe, America and Asia [16, 17].

Viral hemorrhagic fever (VHF) is characterized by severe multiple organ dysfunction syndrome. Etiologically, four particular RNA viral families (Arenaviridae, Bunyaviridae, Filoviridae, and Flaviviridae) lead to VHF. The viruses that cause VHFs are spread across most of the globe. Haemorrhagic viruses are considered as potential biological warfare agents. Initially, clinical symptoms include fever, cephalgia, myalgia, arthralgia and chills, which can lead to massive haemorrhages, shock or even acute multiple organ dysfunction. Paraclinical parameters show an increase in liver enzymes and a decrease in albumin levels. The coagulation panel shows an increase in prothrombin time and a decrease in fibrinogen. These results of the paraclinical tests may be similar to diseases like disseminated intravascular coagulation, malaria, haemolytic uremic syndrome. Although the confirmation of the diagnosis requires detection of viral RNA, viral antigens, or specific antibodies, the clinician must raise the suspicion quickly, before laboratory results, because these diseases require strict isolation measures and biosafety level 4 laboratory facilities [18].

Dengue fever is a global arboviral infection spread by the mosquito genus Aedes (A) (primarily A. aegypti, but also A. albopictus, and A. polynesiensis), a mosquito found in the tropical and subtropical regions of the world, also involved in spreading Zika virus disease, yellow fever, and Chikungunya. About 40% of the world population, almost 3 billion people live in regions with a dengue threat [19]. In more than 100 countries, people are affected by dengue fever resulting in up to 22,000 deaths per annum globally [20]. In 2018, Romania reported 4 cases of dengue fever, all travel-associated [21]. With incubation of 3-14 days, 50-80% of patients are asymptomatic during the period of illness [22]. Classic dengue fever (break-bone fever) is distinguished by high fever, severe cephalgia, myalgia, arthralgia, retro-orbital pain, abdominal pain or tenderness with persistent vomiting, and hepatomegaly. The diagnosis is supported by the combination of thrombocytopenia, leukopenia, modifications of the liver function tests and serological tests for dengue virus.

Yellow fever virus etiologically belongs to Flaviviridae family, which causes acute viral disease transmitted by A. aegypti, and Haemagogus mosquitoes. The name's "yellow" refers to jaundice that affects most patients. In tropical regions of Africa and Central and South America, the virus is endemic. In 2018, one case of yellow fever was reported by Romania [21]. Severe cases can have a mortality rate of up to 50% [23, 24]. With an incubation period of 3-6 days, clinical manifestations in the second phase, which generally affect liver and kidney, consist in fever, vomiting, abdominal pain, jaundice, dark urine, hemorrhage, and even shock. Yellow fever, especially during early stages, is difficult to diagnose, it can be mistaken for diseases like leptospirosis, fulminant forms of viral hepatitis, or even severe malaria. Confirmation of the diagnosis requires the detection of the virus by identifying viral ribonucleic acid (RNA), specific antigen or immunoglobulins M.

Digestive infections caused by protozoans and parasites

Parasitic infections causing diarrhea are particularly important in young children, immunocompromised patients, and those living in conditions of poor sanitation and hygiene, with unsafe food and water supplies. Travelers from developed countries are another group at risk, particularly susceptible to parasitic pathogens, because they lack protective immunity acquired from previous exposure. Several of these organisms are of zoonotic origin, and there may be occupational or recreational exposure risks [25].

Giardia lamblia, Cryptosporidium spp., Entamoeba histolytica and Dientamoeba fragilis are the most important diarrhoea-causing protozoans. Helminths are less important as agents of diarrhea, but they may produce loose or even dysenteric stools in acute or heavy infections (for example, intestinal schistosomiases). One important exception is the nematode Strongyloides stercoralis, which has the unusual capacity to maintain subclinical infections for years or decades, being discovered only when the patient is immunosuppressed for various reasons, when severe or potentially fatal disseminated infection may occur [26].

Giardia lamblia infections (synonym G. Intestinalis, G. duodenales) in developed countries occur in 6-8% of children and 2% of adults, and around 33% of the population is infected with protozoans [27, 28]. In the US for example, CDC estimated 77,000 cases/year of Giardiasis [29].

One of the several species of the genus Cryptosporidium is

Cryptosporidium parvum, which, together with C. hominis, are the most common cause's ofcryptosporidiosis in humans [29]. Similar clinical symptoms could reveal infections by other Cryptosporidium spp. such as C. felis, C. meleagridis, C. canis, and C. Muris.Around 748,000 cryptosporidiosis cases/year occurred in the US [30, 31].

The causative agent of amoebiasis is Entamoeba histolytica - the only human pathogenic species of the genus Entamoeba. Amebiasis has a worldwide distribution, prevalent in Central and South America, Africa, and Asia, being produced by trophozoites of Entamoeba histolytica.

Clinical manifestations can appear up to 4 months from the contact with contaminated food or objects. In about 90% of cases, the disease may evolve asymptomatic, self-limiting, with recurrences. The rest of the patients may have different severity clinical forms, such as acute colitis (bloody diarrhea, fever, abdominal pain), severe colitis (fulminant, abscesses), and chronic form (ameboma, and inflammatory bowel disease). The etiological diagnosis is based on the microscopic identification of cysts and trophozoites in the stool of the patients, specific antibodies and antigens detection. Around 50 million people worldwide suffer from amoebiasis each year, resulting in 100,000 deaths each year [32].

One of the most underestimated diarrhea-causing protozoansis Dientamoeba fragilis and recent studies demonstrated the direct implication as a common cause of gastrointestinal disease and, in the meantime, his pathogenic potential.The prevalence of Dientamoeba fragilis varies from 0.3% to 52% and often exceeds that of Giardia lamblia [33].

Malaria is produced by infection with Plasmodium species, by the bite of Anopheles mosquito, being recognized as the second cause of death by infections in Africa. According to the European Centre for Disease Prevention and Control (ECDC), Romania confirmed and reported 18 cases of malariain 2018 [21]. The disease is endemic in sub-Saharan Africa and South Asia and has an incubation period between 8-25 days, with a clinical picture dominated by cyclical fever. The following manifestations: insomnia, weakness, arthralgias, myalgias, diarrhoea, abdominal pain, headache, and hepatosplenomegaly can be associated with the fever in case of acute malaria. Classical clinical triad present in malaria consists of fever, splenomegaly, and anaemia. The microscopic examination of thin or thick blood smears, the detection of the parasite nucleic acid by real-time polymerase chain reaction assay, the identification of the plasmodium antigen by immunochromatography are specific tests used to confirm the diagnosis of malaria [34].

Leishmaniasis is a neglected tropical disease, protozoan vector-borne infection, whose transmission is through the bite of an infected female sand fly (Phlebotominespecies). It is present in environments ranging from tropical forests in South and Central America to desert areas in West Asia, including North of Africa with cutaneous leishmaniasis, which is the most common form, mucocutaneous, and visceral leishmaniasis, the last one being the most severe form of the disease. The period of incubation varies widely, from a few weeks to several months after the initial bite, depending on the species. The wide spectrum of clinical manifestations in visceral leishmaniasis includes fever, anorexia, abdominal pain, emesis, diarrhea, hepato-splenomegaly. Diagnostic findings are based on skin biopsy, tissue culture, and presence of antibodies [35].

Dracunculiasis, also known as Guinea worm disease, can be found in rural areas of South Sudan, Chad, Ethiopia, and Mali, which relies on contaminated water supplies. Clinical symptoms can take up to a year to appear, and may include painful blister centered on the worm, usually localized in the lower extremity, fever, nausea, vomiting, and local lymphadenopathy [36].

Schistosomiasis is a disease caused by parasitic worms (Genus Schistosoma), also known as bilharzia, which is endemic in tropical and subtropical areas and considered as one of the neglected tropical diseases. With an incubation period of about 2-8 weeks, the acute clinical picture presents a flu-like syndrome, nausea, vomiting, abdominal pain, bloody diarrhoea, hepatosplenomegaly, and lymph-adenopathy. Laboratory findings include the direct detection of eggs by the microscopic examination or of the parasite's nucleic acid in patients'stool and urine, and serological tests for identifying the specific antibodies in patients returned from endemic areas, but without eggs demonstrated in faecal or urine samples [37].

Digestive infections caused by bacteria

One of the most common bacterial causes of gastroenteritis worldwide is Campylobacter spp. frequent especially in children under 2 year-old, causing diarrhoea, abdominal cramps, vomiting, fever and even bleeding. It is usually generated by the consumption of raw or undercooked meat (frequent/especially poultry) or contaminated milk.

Up to 25% of cases of antibiotic-associated diarrhea in healthcare institutions and hospitals are generated by Clostridium difficile. Elderly and immunocompromised patients have a higher risk. The most recent emergence of highly toxigenic and resistant C. difficile strains has led to more severe outbreaks, increasing mortality and morbidity [38].

In the developing countries, especially among children, Escherichia coli is a major cause of diarrheal disease and the leading cause of travellers'diarrhoea. The infections are produced by drinking water contaminated with human or animal feces. A special strain of this genus is Escherichia coli O157:H7, a Shiga toxin producing. These bacteria generate gastrointestinal infections with symptoms including vomiting and sometimes even bloody diarrhoea. Although it is usually cured after a few days, a percentage of 5-10% of infections lead to haemolytic uremic syndrome and its consequences (destruction of blood platelets, anaemia, kidney failure) [39].

Helicobacter pyloriis the main cause of gastritis and is associated with the development of gastric and duodenal ulcers or even stomach cancers. H. Pylori is the strongest etiological factor in both of these conditions, with the World Health Organization classifying it as a class I carcinogen. According to the CDC, approximately two-thirds of the population is infected with H. pylori, but less than 20% have a risk of developing ulcers or stomach cancer [40]. On the other hand, infection with H. pylori may protect against some cancers, such as oesophageal adenocarcinoma and gastroesophageal reflux disease [41]. It can cause stomach pain or nausea, but in many cases, there are no symptoms.

Salmonella and Shigella are food-borne GI illnesses. Salmonella is common and is found in raw meats, poultry, seafood and eggs, as well as milk and dairy products. Acute symptoms include nausea, vomiting, abdominal cramps, diarrhea, fever, and headache. Shigella is frequently found in water polluted with human feces. Symptoms of shigellosis or bacillary dysentery include abdominal pain, cramps, diarrhoea, fever, vomiting, and blood, pus, or mucus in stool.

Yersinia enterocolitica is a cause of diarrhea and abdominal pain relatively frequent after eating contaminated food, especially raw or undercooked pork products, milk or ice cream. Common symptoms are fever, abdominal pain and diarrhea, which is often bloody.

The most common cause of food intoxication, characterized by violent onset, severe nausea, cramps, vomiting, and diarrhea is Staphylococcus aureus. It is also associated with a large range of food, and could be found on humans (infected cuts, skin, throats and noses).

Brucellosis is a zoonosis caused by four different species of Brucella. It is considered as a major infectious disease in the Caribbean, the Middle East, Eastern Europe, Asia, and Africa. According to ECDC, one case of brucellosis was reported by Romania, in 2018 [21].The incubation period is between 2 weeks to 5 months. General brucellosis signs are usually vague and flu-like, with gastrointestinal symptoms such as dyspepsia, diarrhoea, constipation, vomiting, abdominal pain, hepatic abscesses. However, the clinical picture is dominated by fever, with undetected aetiology through routine laboratory investigations. The diagnosis of brucellosis, although easy to confirm based on serological tests, often requires a period of up to one year, due to the presence of a polymorphic, sometimes oligo-symptomatic clinical picture.

Leptospirosis is a global zoonotic infection with a high prevalence in Caribbean and Pacific islands, Central and South America, Southeast Asia, predominantly during the rainy period, caused by pathogenic spirochetes of genus Leptospira. In 2018, 51 cases of leptospirosis were confirmed in Romania [21]. Usually the incubation period is 1-2 weeks. It presents with a wide range of clinical symptoms, which could be easily mistaken for other diseases, including flu-like syndrome, nausea, vomiting, diarrhoea, rash, dry cough, jaundice, hepatomegaly and splenomegaly, oliguria/anuria, haemorrhages, with the involvement of multiple organs. Suspicion occurs in the case of association between digestive, liver, kidney manifestations with fever, and myalgia. Confirmation requires the determination of specific antibodies.

DIAGNOSIS

In the presence of symptoms of a possible gastrointestinal infection, the diagnosis could be confirmed by different old and modern laboratory tests using stool specimens first and others such as serum for specific antibodies (serological tests). The standard culture to isolate bacteria remains the gold standard for bacterial pathogens, even if it has a relatively low sensitivity and it is time-consuming (more than 24 h), but it may be followed by antibiotic susceptibility testing. In this way, the therapeutic options may be evaluated, but also the assessment of microbial resistance to antibiotic therapy [42]. Ova or parasite examination are ordered in case of suspicion of parasites. For this purpose, a direct examination by microscopy or a concentration method is used, but it has a low sensitivity and it is, once again, time consuming and requiring specific training of the laboratory staff. In addition, there are antigen tests used to detect Clostridium difficile (GDH, toxins), Giardia lamblia, Cryptosporidium spp., Helicobacter pylori, or Entamoeba histolytica. However, antigen tests can only detect a few specific parasites and therefore cannot replace ova and parasite examination. Antigen tests are useful to rapidly detect viruses causing gastroenteritis, such as rotavirus and adenovirus; however, these tests are not available for all entero-pathogens and show a variable sensitivity.

Taking into account the wide range of pathogens that can cause diarrhea and the similarity of the clinical manifestations produced by different pathogens; the molecular techniques seem to be the best tools for a rapid diagnosis. In the last years, some tools based on polymerase chain reaction (PCR) techniques have been developed to detect specific microorganisms or a panel of different entero-pathogens directly from stool samples [43-45]. Real-time PCR allows the simultaneous detection and differentiation of viral, bacterial and parasitic gastrointestinal pathogens. This assay also showed a high sensitivity for most pathogens included in the panel and efficient detection of coinfections. The main advantages of the molecular tools for the diagnosis of gastroenteritis are: high sensitivity, increased diagnostic spectrum, improved workflow (processing and diagnosis time is between 1 and 5 h), favorable impact on infection control and costs. Some disadvantages of molecular methods are the inability to distinguish between viable and nonviable microorganisms; they do not offer antibacterial susceptibility or epidemiological data; high cost; detection of the asymptomatic carriage could be difficult to distinguish from symptomatic/asymptomatic infections. Therefore, the application of these tools should be performed in patients selected based on clinical condition and/or the severity of gastroenteritis. Particularly in hospital settings, the rapid diagnosis provides important information for implementing infection control measures [46-48].

The clinical symptoms of all these diseases are nearly identical. Thus, it is difficult and almost impossible to determine the pathogenic cause based on clinical features alone. Rapid diagnosis, appropriate treatment, and infection control are important measures in these contexts. The early medical challenge is to include the possibility of tropical infectious diseases that are not common in the area, in the differential diagnosis. Not only the characterization of the symptoms but also the detection of infectious diseases based on a detailed history of the patient and a quick assessment can enormously help the clinicians in establishing a correct diagnosis and treatment.

Emerging evidence suggests that many gastrointestinal diseases are associated/caused by alterations in the gut microbiome. Specific microbiome signatures have been reported for irritable bowel syndrome and inflammatory bowel disease, and these have been associated with pro and anti-inflammatory effects, contributing to disruption or maintenance of gut homeostasis. Colorectal cancer is the third most common malignancy diagnosed worldwide, one of the leading causes for cancer-related mortality in both men and women. Different hereditary, environmental and inflammatory factors have been shown to increase the risk of colorectal tumorigenesis, but recently, bacteria and viruses have been described to be involved in colorectal carcinogenesis through direct modulation of epithelial cells, leading to genomic or chromosomal instability. Observational studies have found positive associations between gastric ulcers, periodontal disease, bacterial infections, and the risk of pancreatic cancer, the most rapid lethal cancer, with over 70% of patients dying within one year after diagnosis.

CONCLUSIONS

Concerning human mobility, several specific aspects must be considered, such as undiagnosed, atypical and subclinical types of diseases. These diseases are mistakenly treated as intercurrent diseases, and serious latent infections may develop. In the last few years, molecular methods have become readily available for many clinical laboratories and their utilization has resulted in a more rapid diagnosis and increased pathogens detection. As travel around the world continues, microbes will continue to evolve, adapting to new environmental conditions. The emergence of new infections will continue, and the distribution, severity and frequency of the identified infections will change, considering the new conditions. Travel or migration of people will continue to be an important factor in the occurrence and development of diseases. The analysis and monitoring of pathogens will focus the specialized actions and researches on the global movement and evolution of microbes. Integration of medical knowledge and multidisciplinary skills – social, biological and physical sciences – are therefore required.

Diagnostic challenges in late presenting diaphragmatic hernia

Patricia Beznea[1], Adrian Campeanu[1,2], Tudor Strimbu[1]

Abstract: *Background: The incidence of congenital diaphragmatic hernia (CDH) has been reported to be 1 in 2000-5000 newborns. The late presentation can occur in 5-30% of all cases and it can be harder to diagnose, as symptoms are usually vague and non-specific.*

Methods: We performed a retrospective review of chart files of all patients admitted to our hospital with the diagnosis of congenital diaphragmatic hernia between 2010 and 2021.

Result: Of the ninety-two cases of CDH treated in our hospital between 2010 and 2021, twenty-six (28%) were late presenting. In the late-presenting CDH group, we found a slight female preponderance, with fifteen female patients (58%) and eleven male patients. A posterolateral left defect in the diaphragm was noted in fifteen cases (58%), a right defect was noted in just one case (4%) and ten patients (38%) were diagnosed with an anterior diaphragmatic hernia. The age at diagnosis varied from 2 months to 14 years. Associated anomalies were noted in just four cases. In all cases, a thoracoabdominal radiograph was performed and ten patients also had a CT scan. Primary repair was performed in 25 of the 26 patients. The mortality rate in our study population was 11%, we reported 3 cases with unfavorable evolution.

Conclusion: CDH presenting beyond the neonatal period is a usual finding and it represents a true diagnostic challenge.

Keywords: *congenital diaphragmatic hernia, late presentation, pediatric*

INTRODUCTION

One of the greatest challenges we face when diagnosing a pediatric patient is the constant concern that an unusual emergent condition, with non-specific symptoms, can easily masquerade as a common condition, and as such, they can be initially misdiagnosed.

Congenital diaphragmatic hernia is a congenital defect that occurs when the pleuroperitoneal canal does not close during the 8th week of fetal development, which allows the herniation of the bowel loops, stomach, solid abdominal organs, or the mesentery into the thoracic cavity. The incidence of CDH has been reported to be 1 in 2000-5000 newborns, accounting for 8% of all major congenital anomalies, with most cases being diagnosed prenatally or soon after birth (approximately 90%) [1–7].

CDH is a common cause of respiratory distress in the neonatal population and is associated with pulmonary hypoplasia, patients presenting with vomiting, tachypnoea, cyanosis, with diminished breath sound on auscultation after birth, but in some cases, it can go undiagnosed until later in life [3]. If CDHs are diagnosed later than 30 days they are considered late-onset CDHs [3, 8]. Late presentation in patients with CDH occurs in 5-30% of all cases, with patient age ranging between 2 months to 12.5 years [1, 3, 5].

Cases of CDH with delayed presentation are usually more subtle and because of that, they can be harder to diagnose [9]. Symptoms, diagnosis, and management of late-

[2] Fundeni Clinical Institute, Bucharest, Romania

presenting CDH differ from those of neonatal CDH and are usually more diverse and non-specific. This usually leads to both clinical and radiological misdiagnosis, which can cause significant morbidity [4, 5, 10]. Massive pneumothorax and pleural effusion are the most common initial diagnosis on a chest radiograph in these cases and often, distinguishing between a CDH or a tension pneumothorax can be difficult and crucial, as the management of these two pathologies differs greatly [1, 3, 8]. Late-presenting CDH can cause acute or chronic respiratory or gastrointestinal symptoms such as dyspnoea, recurrent pulmonary infections, chest pain, postprandial fullness, or abdominal pain [2, 10].

This study aims to emphasize the fact that diagnosing CDH outside de neonatal period is often difficult and to help familiarize healthcare professionals with the clinical presentation that can occur in these cases to help facilitate early management and avoid misdiagnosis

MATERIALS AND METHODS

We performed a retrospective review of chart files of all patients admitted to our hospital with the diagnosis of congenital diaphragmatic hernia between 2010 and 2021. Patients who developed symptoms and were diagnosed in the first month of life were classified as having early presenting CDH, while those who were diagnosed after one month of age were considered to have a late-onset CDH. Only patients with late-presenting CDH age were included in our study. Patients with diaphragmatic eventration, hiatal hernia, or paraesophageal hernias were excluded from the study. Patient demographics, treatment, and outcome were then reviewed.

RESULTS

Of the ninety-two cases of CDH treated in our hospital between 2010 and 2021, twenty-six (28%) were late presenting. In the late-presenting CDH group, we found a slight female preponderance, with fifteen female patients (58%) and eleven male patients. A posterolateral left defect in the diaphragm was noted in fifteen cases (58%), a right defect was noted in just one case (4%) and ten patients (38%) were diagnosed with an anterior diaphragmatic hernia. The age at diagnosis varied from 2 months to 14 years. The patients were divided into 3 age groups: under 1 year, between 1 and 5 years, and over 5 years. We found that patients under the age of one presented with either left-sided defects or with an anterior hernia. In the case of patients with ages between 1 and 5 years, left-sided defects were more frequent than right-sided defects or anterior hernias, the same being the case for patients older than 5.

Associated anomalies were noted in just four cases: two patients had a history of esophageal atresia repair in the neonatal period, one patient presented with Down syndrome, and one patient presented with cardiac anomalies that did not require surgical correction.

Table 1 illustrated the relationship between age and location of the defect.

Table 1: The relationship between age and location of the defect

Age	Anatomical variant CDH		
	Left	**Right**	**Anterior**
< 1 year	2	0	5
1-5 years	9	1	3
> 5 years	4	0	2
Total number of patients	15	1	10

Clinical presentation in late-presenting CDH was mixed and various as can be seen in Table 2. For that reason, we dived the patients into four main categories as follows: 8 patients (31%) with respiratory symptoms, 6 (23%) with digestive symptoms, 6 (23%) with both, and 6 (23%) were asymptomatic.

Table 2: Classification of symptoms

Symptoms	Number of cases	Details
Respiratory	8	
Acute	6	Dyspnea 4 Cough 3 Febrile URTI 3
Chronic	2	Chronic respiratory distress
Gastrointestinal	6	
Acute	6	Vomiting 5 Abdominal pain 3 Loose stools 1
Chronic	0	
Both	6	
Acute	4	Dyspnea Vomiting Abdominal pain
Chronic	2	Failure to thrive + abdominal pain + chronic respiratory distress
Asymptomatic	6	

URTI – upper respiratory tract infection

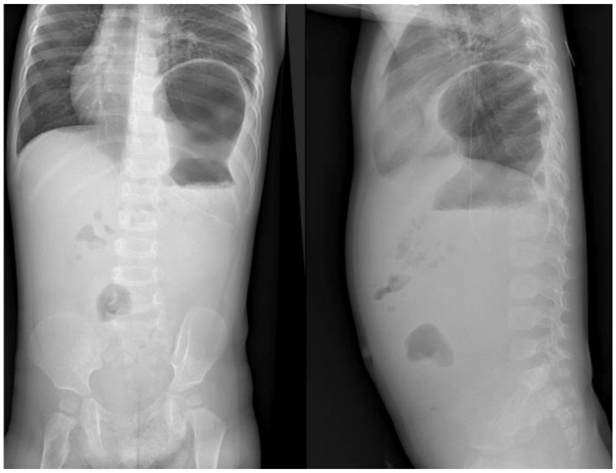
Table 3 shows the site of the hernia concerning the presenting symptoms. Of the six patients presenting with gastrointestinal symptoms, five had a left-sided defect, and just one patient presented with an anterior hernia, while of the eight patients presenting with respiratory symptoms, four were found to have a left-sided defect, and four presented with an anterior hernia. The patient who was diagnosed with a right-sided defect presented with both respiratory and digestive symptoms. We found three patients with a left-sided defect and four patients with an anterior defect that were asymptomatic and were diagnosed incidentally when a chest radiograph was performed when monitoring another pathology.

Table 3: The relationship between symptoms and location of the defect

Symptoms	Right	Left	Anterior
Respiratory	0	4	4
Gastrointestinal	0	5	1
Both	1	4	1
Asymptomatic	0	2	4

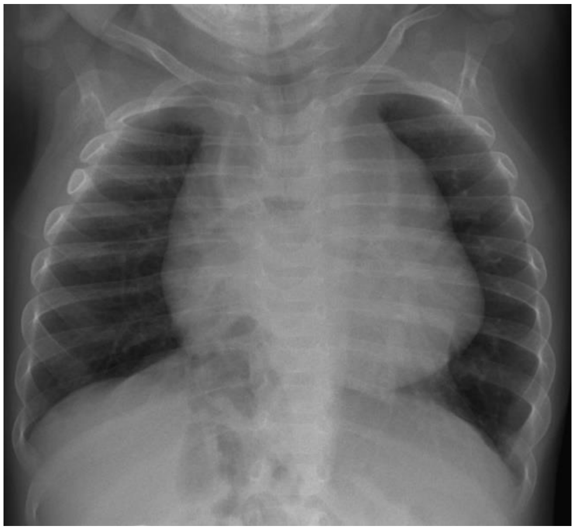
In all cases, a thoracoabdominal radiograph was performed and it should be mentioned that almost half of our patients had previous chest radiographs performed routinely for other conditions that were normal at that time. (Figure 1, Figure 2) Ten patients also had a CT scan that confirmed the diagnosis of diaphragmatic hernia and four patients had upper gastrointestinal contrast studies performed. It bears mentioning that all the patients with upper GI contrast studies were admitted to our hospital at the beginning of the study period. In the last 7 years, upper GI contrast studies have not been performed to diagnose a late-presenting diaphragmatic hernia.

Figure 1: Chest radiograph showing left-sided diaphragmatic hernia



Primary repair was performed in 25 of the 26 patients. The open abdominal approach was favored in most cases (76%), while only six patients were operated on by minimally invasive techniques. Out of the six, four patients underwent laparoscopic approach, and two patients underwent thoracoscopic approach.

Figure 2: Chest radiograph showing anterior diaphragmatic hernia

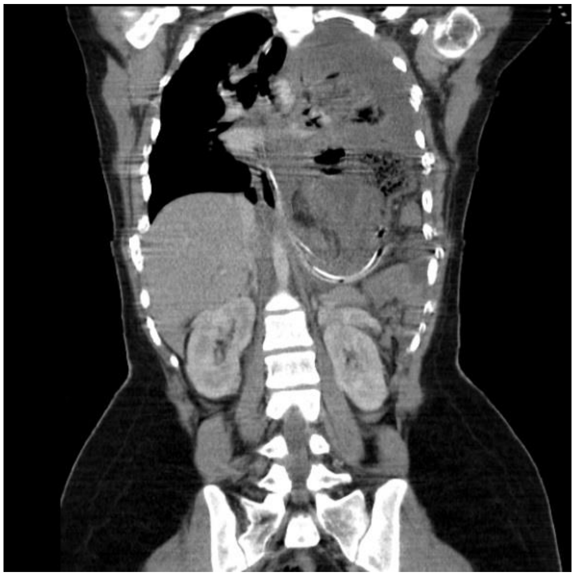


The mortality rate in our study population was 11%, with all three patients had presented with severe complications such as gastric volvulus. In the remaining patients, we identified just one case of pleural effusion after thoracoscopic approach that required drain placement, with no further complications being observed later on.

We report the cases of the three patients that had an unfavorable outcome.

The first case was that of a 14-year-old girl with a history of 3 days of diffuse abdominal pain and vomiting. On admission, clinical examination showed respiratory distress with diminished breath sounds on the left side. The patient went into cardiocirculatory arrest soon after admission that was successfully managed by external chest compressions and resuscitation drugs. Chest and the abdominal radiograph showed a hydroaeric image and the tip of the nasogastric tube situated in the left hemithorax, with no stomach bubble present in the abdominal area. A thoracoabdominal CT scan was performed to confirm the diagnosis of the left diaphragmatic hernia (Figure 3). Emergency surgery by laparotomy revealed a large left diaphragmatic defect with a herniated stomach. After stomach reduction into the abdominal cavity, a large quantity of blood was evacuated from the left thoracic cavity. The stomach was almost completely necrotic, perforated, and presented with thrombosis of the gastric vessels. Subtotal gastrectomy with oesophageal-gastric anastomosis and diaphragmatic defect suture was performed, but the postoperative outcome was unfavorable, the patient dying on postoperative day 10 due to multiple organ dysfunction syndrome and cardiac arrest.

Figure 3: CT scan showing a left-sided defect in the diaphragm with herniation of the bowel and stomach



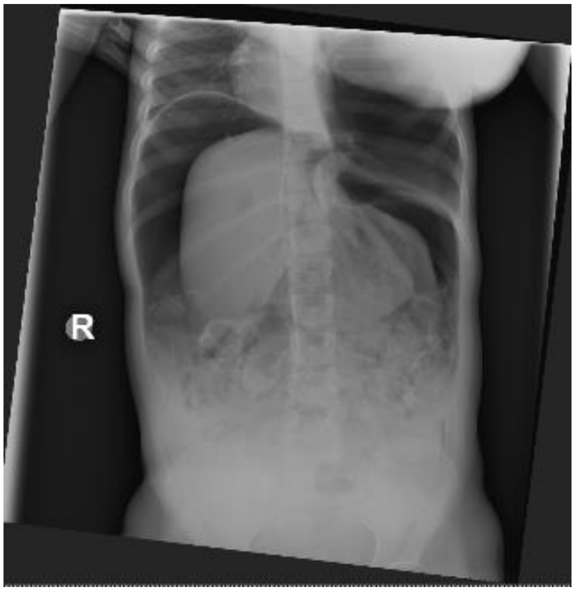
The second case was that of a 6-year-old girl with a history of abdominal distension, diffuse pain, and vomiting. On clinical examination, the patient presented with abdominal distension and diffuse abdominal pain with tenderness on palpation, dyspnoea, and paleness.

An abdominal radiograph showed a tension pneumoperitoneum, with an elevation of the left hemidiaphragm and collapsed bowel loops in the hypogastric region (Figure 4).

The patient was immediately taken into the operating room. She presented with severe bradycardia and went into cardiac arrest, which was managed by orotracheal intubation, external chest compressions, and resuscitation drugs. After 10 minutes, cardiac activity reappeared, and emergency laparotomy was performed. Intraoperatively, a large quantity of gastric liquid and chyme was evacuated from the peritoneal cavity. A large left diaphragmatic defect (10/6 cm) was found, with herniated stomach, spleen, and left hepatic lobe. After the reduction of the herniated content, a large perforation of the stomach was noted. A partial gastrectomy with diaphragmatic defect sutures was performed.

After surgery, the patient developed intravascular disseminated coagulation and acute renal failure, and 24h after admission she went into cardiac arrest that did not respond to resuscitation maneuvers.

Figure 4: Tension pneumoperitoneum with a left diaphragmatic hernia and gastric perforation



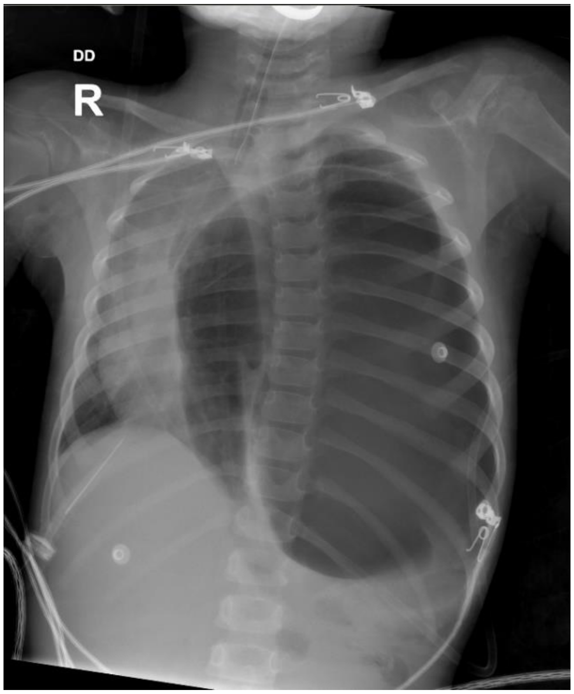
The third case was that of a 4-years-old patient who presented to the emergency room for diffuse abdominal pain and vomiting. An ultrasound was performed in the emergency room than normal. Due to the latest COVID 19 guidelines, the patient was admitted to the COVID ward, while awaiting her PCR test results. Six hours after admission, she went into cardiac arrest and the resuscitation protocol was started with external chest compressions and iv drugs administration. The patient was intubated, and a chest radiograph was performed that showed large hyper transparency in the left hemithorax with an important mediastinal shift to the right, with an imprecise contour of the left diaphragm (Figure 5).

Since the patient could not be ventilated after intubation and because of the image on the chest radiograph, the decision was made to insert pleural drainage. After the tube was inserted, the patient was stabilized.

A contrast substance was given through the nasogastric tube and showed extravasation of the contrast substance into the abdominal cavity, with an imprecise left diaphragm and a smaller hyper transparency in the left hemithorax. The diagnosis of gastric perforation was made and the patient was prepared for surgery. Before she could be taken into the operating room the patient went into cardiac arrest, but after multiple attempts of stabilization, she did not respond to resuscitation maneuvers.

Post mortem examination revealed a left diaphragmatic defect with a perforated stomach due to gastric volvulus.

Figure 5: Tension gastrothorax



DISCUSSION

A congenital diaphragmatic hernia occurs because of the incomplete closure of the pleuroperitoneal canal during fetal development [11]. Diaphragmatic closure is usually complete by the ninth week of gestation, with the left side closing one week after the right side [12].

During the neonatal period, CDH is the most common cause of respiratory distress, and it can result in high mortality rates in this age group. In most cases, the diagnosis of CDH is established during fetal development or early in the neonatal period [11].

The classification of CDH includes 4 types of patients as follows:

- Type 1 – when the herniation occurs in the early period of fetal development, resulting in pulmonary hyperplasia and increased risk of perinatal death

- Type 2 – when the herniation occurs in the late period of rapid bronchial division, resulting in unilateral pulmonary hypoplasia and pulmonary hypertension

- Type 3 – when the herniation occurs during the late stages of gestation or early in the neonatal period; some patients can present with mild respiratory symptoms at birth, others may not present problems during the neonatal period

- Type 4 – when the herniation occurs after the neonatal period; these patients have no pulmonary hypoplasia [11, 13]

The incidence of late-onset CDH varies from 5 up to 45.5% [8, 9, 11]. There is a 2:1 male to female ratio in both left and right-sided hernias, with 32.7% of cases presenting with hernia sacs [11, 14, 15]. In our case series, we found a slight female preponderance.

Localization on the right side of the defect is more frequently encountered in patients with late-presenting CDH. Patients with right-sided CDH become symptomatic at a younger age compared to patients with left-sided defects [14]. In our study, most of the patients presented with left-sided defects (15 cases) and anterior defects (10 cases). There was just one case of right-sided hernia, in a 9-year-old patient.

Late-onset CDH is difficult and intriguing to diagnose due to various, nonspecific, vague, and misleading clinical presentations, with an array of symptoms that are not pathognomonic for this defect, making it a difficult diagnosis [4, 16–20]. Misdiagnosis of these cases is not uncommon (according to some reported occurring in 62% of cases) and can result in increased morbidity with herniated bowel necrosis, peritonitis, respiratory arrest, and, in some cases, even death [3]. A high index of clinical suspicion and a chest radiograph is essential in establishing a diagnosis [6]. Initial symptoms in patients with CDH can be respiratory (coughing, wheezing, frequent upper tract infections, dyspnea), gastrointestinal (abdominal pain, vomiting, nausea, constipation, failure to thrive), or a combination of the two [5, 21]. Symptoms of late presenting cases are often misleading, and patients are often treated for other conditions with similar symptoms [21]. There have been studies reporting a higher incidence of respiratory symptoms in younger children and right-sided hernias and gastrointestinal symptoms in older children as well as in those presenting with left side CDH [4, 18, 22–24]. 10-11% of patients may be asymptomatic at the moment of diagnosis [21, 25].

Our study population is too small to obtain statistical significance in this regard. Patients with left-sided defects presented with either respiratory symptoms, digestive symptoms, or both. Most patients with anterior defects presented with respiratory symptoms and, in the single case of right-sided diaphragmatic hernia we encountered, our patient presented with both respiratory and digestive symptoms. Four of the youngest patients in our study were asymptomatic, while one presented with respiratory symptoms and two presented with both respiratory and digestive symptoms.

Late-onset CDH presenting with gastrointestinal symptoms have a smaller hernia defect and the symptoms are usually caused by different degrees of obstruction secondary to incarceration [4].

A smaller defect can prevent herniation of the viscera, either due to the existence of a hernia sac that confines the viscera or secondary to occlusion of the defect by solid organs (such as the liver or the spleen), but in some cases, when the abdominal pressure increases (during coughing, sneezing or other strenuous activities) bowel may herniate into the thoracic cavity [1, 24, 26]. The patient may become symptomatic when the actual herniation occurs either after a hernia sac rupture or due to complications of the herniated content such as volvulus or strangulation [1]. The hernia may be intermittent and as such, a normal radiograph does not necessarily exclude the diagnosis [5, 6, 27]. In our cases series, more than half of our patients had normal previous chest radiographs.

Kim et al. reported that 23% of patients with late-onset CDH present with associated congenital malformations such as intestinal malrotation, cardiac defects, pulmonary hypoplasia, chromosomal anomalies, and urogenital anomalies, while others reported an increased prevalence between 8-80% [16, 24, 28-31]. Studies have shown that there is a lower incidence of associated anomalies in late-onset CDH when compared to early-onset CDH, diagnosed in the neonatal period [13, 31]. In our case, just two patients presented with a history of esophageal atresia repair.

Chest radiograph supplemented by additional imaging such as CT scan can be a useful diagnostic tool in the differential diagnosis of thoracic lesions such as lower lobe pneumonia, pneumothorax, pleural effusion, or other lung lesions [11, 22, 32].

There have been reports when CDH was misdiagnosed as pneumothorax and chest tubes were inserted into the thoracic cavity, which lead to morbidity in some cases. [6] Distinguishing between these two entities is extremely important as the management of these two conditions is different [3, 18, 24, 33]. Baglaj et al. reported that chest radiographs diagnose only 49% of cases, with almost 25% of them being diagnosed with other conditions [21, 34, 35].

If a chest radiograph fails to establish the diagnosis, upper gastrointestinal series or contrast-enhanced CT scans can be used to diagnose CDH [4]. Upper gastrointestinal studies are considered unnecessary in the neonatal period but have been recommended in older children [14]. Performing a CT scan means a high radiation burden for the patient, but this is a useful imaging modality that can bring important information regarding the anatomy of the defect, which helps in preoperative planning [3, 13]. Chest radiographs were performed in all cases and CT scans were performed in 10 cases to confirm the diagnosis. Contrast studies were not performed in four cases, but these patients were patients who had been diagnosed in the early years of our study period.

Once the correct diagnosis has been established, patients with late-onset CDH have a more favorable prognosis due to the less severe or the absence of pulmonary hypoplasia [8, 11, 18, 36]. In the case of late-onset CDH, a 3.6% postoperative complication rate was reported, with a 1.9% recurrence rate and a 1.95 mortality rate [37]. In our study, the mortality rate was higher, with patients having had an unfavorable outcome. Just one patient in our series presented with postoperative complications (pleural effusion) that was resolved by placing pleural drainage.

Late-presenting CDH is prone to rare complications such as tension gastrothorax, gastric perforation, splenic torsion or rupture, intestinal obstruction, or bowel necrosis [4, 27].

When the stomach herniates in the thoracic cavity, it can become distended resulting in tension gastrothorax. Acute gastric volvulus is a possible complication of patients with late-presenting CDH. Such cases are rare but can have important, life-threatening complications. The distended stomach leads to severe respiratory distress. Okuda et al. reported a case of a patient with acute tension gastrothorax with cardiopulmonary arrest and failed resuscitation. An acute gastric volvulus is a surgical emergency, with non-operative management being associated with an 80% mortality rate. There is also a risk of mediastinal spillage, with possible rupture of major blood vessels [13]. The first step in managing such patients is the immediate decompression of the stomach, reduction of the volvulus, and treatment of the underlying cause. The association of gastric volvulus and CDH is extremely rare, with only 27 pediatric cases having been reported thus far. This association can occur due to the absence of elongation of 2 of the 4 ligaments supporting the stomach (gastrophrenic and gastrosplenic) [13]. Two of our patients presented with this complication, with unfavorable outcomes [11, 27, 38, 39].

Surgical management is necessary to correct the defect and prevent further complications [20]. The type of approach varies in different centers and even in the same center among different surgeons. No consensus has been reached regarding the best approach for late-onset CDH. The current recommendation is for each surgeon to decide on the type of surgery based on one's experience and the patient's history [23, 40]. Thoracotomy allows for safer surgery when dissecting adherences between the abdominal viscera and the mediastinal contents. This approach is particularly useful in recurrent hernias, with some cases even requiring a combined thoracoabdominal approach [12].

For elective repair, the indication is to perform minimally invasive surgery [40]. Some studies have shown an increase in recurrence rate in minimally invasive surgery for the repair of CDH of 5-23.1%, with a higher rate in cases of thoracoscopic repair [9, 26, 41]. In their study, Obata et al. reported a higher recurrence rate after the laparoscopic approach, most likely due to difficult visualization of the posterolateral defect [23, 42].

Twenty-five of the twenty-six patients in our series underwent surgical repair of the diaphragmatic defect, nineteen by open abdominal approach, four by laparoscopic approach, and two by thoracoscopic approach. None of our patients presented with postoperative recurrence. There are some controversies when using the thoracoscopic approach regarding chest drainage placement, with some studies reporting good results with tube placement, while other authors suggest that the residual pneumothorax will spontaneously be resorbed, and the placement of the chest tube can cause negative intrathoracic pressure that can increase the risk of recurrence [9, 11]. In the two cases that were resolved by the thoracoscopic approach in our series, there was no tube placement, but one patient presented with postoperative pleural effusion that required a second surgery with fluid drainage and tube placement. After tube placement, the patient presented with no further complications

CONCLUSIONS

CDH presenting beyond the neonatal period is a usual finding and it represents a true diagnostic challenge, as the clinical presentation is non-specific, and misdiagnosis is a frequent occurrence and should always be considered as a differential diagnosis in different clinical settings. Raising awareness of late presenting diaphragmatic hernia may be key to improving prognosis and avoiding medical errors.

Diagnostic difficulties in c-kit negative gastrointestinal stromal tumors: report of four cases

Andreea C. Iorgescu[1], Vlad Herlea[1,2], Elena Stoica Mustafa[1], Catalin Pechianu[1,2], Alexandru Procop[1], Maria Sajin[3,4], Irinel Popescu[1,2]

Abstract: *Introduction: The gastrointestinal stromal tumors (GIST) are dominated by KIT and PDGFRA mutation. The immunohistochemical detection of CD117, a protein express by KIT gene, is essential for the diagnosis and those that are negative always represented a diagnostic challenge*

Case reports: In this article we present a series of 4 cases of CD117 negative GIST tumors, diagnosed and surgically resected in Fundeni Clinical Institute and an overview of the histogenesis, diagnostic problems and management of c-kit negative GIST. All patients were males and the tumors were located in the stomach and small bowel.

Conclusion: It is important for the pathologists to beware of the fact that a CD117 negative in the context of a typical morphological appearance does not exclude a GIST tumor and also the oncologist must be aware not to exclude the therapy with imatinib based on the negativity of CD117.

Keywords: *GIST, gastrointestinal stromal tumors, c-kit negative, CD117, DOG1, immune-histochemistry*

INTRODUCTION

GISTs are rare tumors accounting for less than 1% of all gastrointestinal tumors but they are the most common mesenchymal tumors of the GI tract.[1] The incidence in Europe and USA is 7-10 cases/1,000,000 [2] and in Korea is 16-22/1,000,000 [3]. Large population based studies from Iceland, Netherlands and Sweden found the incidence to be 11, 12.7 and 14.5 cases/1,000,000 [4,5,6]. However there are studies that explain this increased incidence by a better diagnosis using modern diagnosis criteria rather than a real increase [7].

The most common age of the diagnosis is between 50 to 60 years old (a mean age of 65) and a peak incidence between 70 and 79, before 20 years old being quite rare ≈ 1% [7,8]

GIST affects both sexes equally [6] though some authors found them to be more common in men [7,9]. They arise most often in the stomach (50-60%) and small intestine (30-35%) but it can occur in any segment of the gastrointestinal tract only with a lower frequency.[10]

Gain of function mutation in KIT or PDGFRA oncogenes lead to ligand-independent kinase activation [11] which gives rise to the majority of GIST. Immunohistochemistry is useful for diagnosis and

typically detects c-kit protein expression, but if the tumor is negative for c-kit, a final diagnosis can be challenging.

In this article we present a series of 4 cases of c-kit negative GIST tumors, diagnosed and surgically resected in Fundeni Clinical Institute and an overview of the histogenesis, diagnostic problems and management of c-kit negative GIST.

CASE REPORTS

In the pathology archives of Fundeni Clinical Institute, between 2004 and 2017 we have traced four cases of c-kit negative GIST. We have examined available clinical data from the hospital database and also HE slides. Immunohistochemically investigations were performed with biotin-streptavidin method [12] in order to assess the phenotype and provide a definitive diagnosis.

Antibody suppliers were Novocastra, and Labvision/Thermo Fisher Scientific as previously reported [13] and the dilutions respected the manufacturer recommendation. The stratification risk according to Miettinen&Lasota (2006) was used [2]. For the mitotic rate we counted the number of mitosis on 50 high power fields (HPF). Tumor cellularity was divided in three categories: spindle, epithelioid and mixed.

Case no. 1

A 47 years old male who presented with lower gastrointestinal bleeding, was investigated with capsule-endoscopy procedure and found with a tumor on the ileum, close to the ileocecal valve. A segmental enterectomy was performed. The surgical specimen was 12 cm long and presented centrally a well circumscribed white nodule of 4/3/4 cm, expanded in the submucosa and muscularis propria with mucosal ulceration. Histologic examination revealed a tumor consisting of spindle cells with a mitotic rate of 1-2/50 hpf. Immunohistochemical stains showed negativity for CD34, CD117, PDGFRA, Desmin, a weak positivity for SMA and a diffuse cytoplasmic positivity for DOG1. The prognostic group was 2, and 7 years later the patient is alive with no recurrent disease.

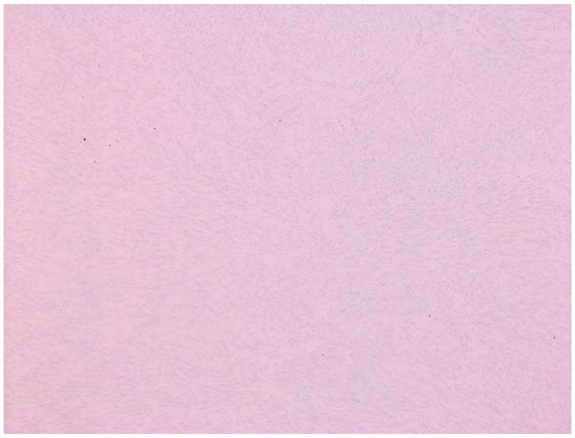
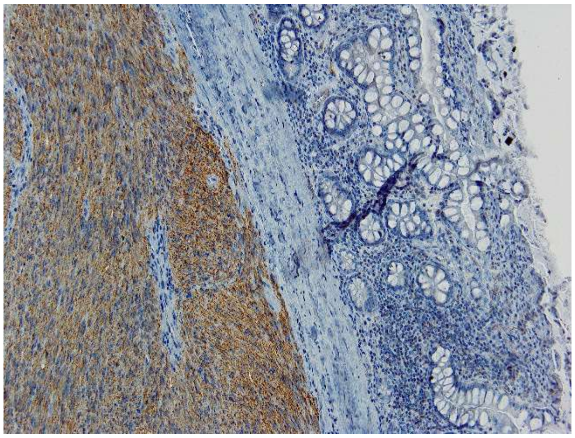
HEx100



CD117x100



DOG1x100

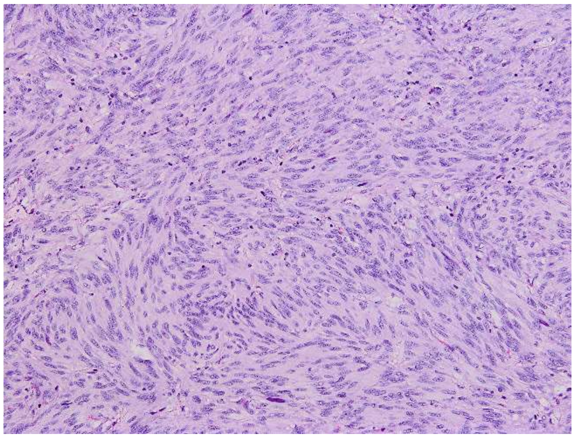
Case no. 2

A 69 years old male presented with abdominal pain, nausea and vomiting for 12 hours before admission. The abdominal CT scan revealed a pelvic tumoral mass on the left paramedian side, developed behind the abdominal wall that involved a small intestinal loop. A segmental enterectomy was performed. The surgical specimen was 30 cm long and presented a solid white tumor with irregular contour 8.5/3.5/2cm with predominantly intramural and subserosal development and focal mucosal ulceration.

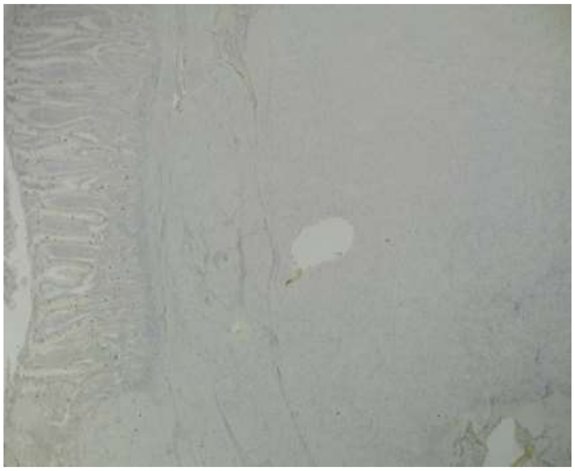
Microscopic examination reveal a mixt morphology with spindle and epithelioid cells, with mild pleomorphism, intratumoral hemorrhagic foci and a mitotic rate of 2/50 HPF.

Immunohistochemical stains were negative for SMA, Desmin and CD117 and positive for DOG1. CD34 and PDGFRA were not done.

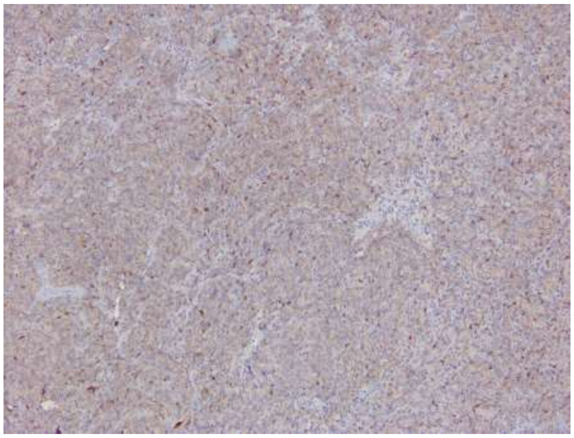
Figures case 2



HEx100



CD117x100



DOG1x100

On the bases of these results the tumor was diagnosed as a c-kit negative GIST with moderate risk (group 3a) and survival from the time of the diagnosis until death was 33 months.

Case no. 3

A 67 years old male was admitted to the hospital with melena, fatigue and weight loss. An esophagogastroduodenoscopy was performed, revealing a 1.5 cm lesion in the gastric fornix.

The tumor biopsy showed a stromal gastric hemorrhagic proliferation associated with a chronic gastritis with Helicobacter Pylori infection.

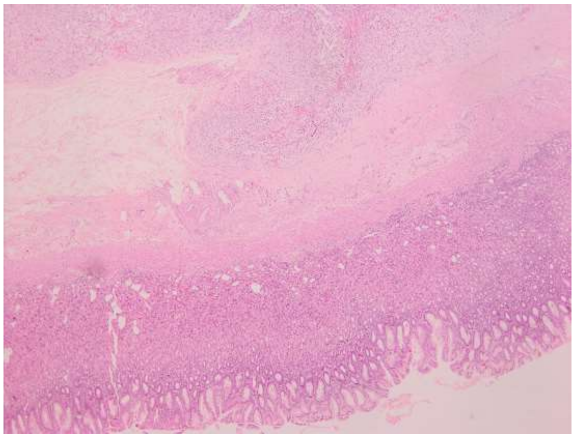
A local excision was carried out and on the surgical specimen was found a firm rubbery white intramural nodule with a diameter of 3/3/3 cm.

Microscopy revealed a tumor proliferation with spindle cell morphology, without mucosal involvement, with 1-2 mitotic figure/50HPF.

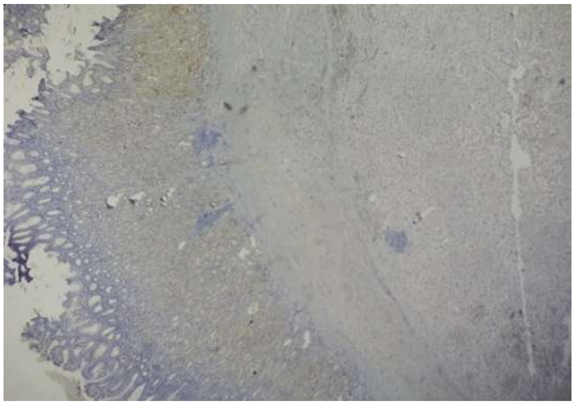
Immunohistochemistry showed negativity for CD117, Actin, Desmin and positivity for DOG1. CD34 and PDGFRA were not done.

The diagnosis of c-kit negative GIST with low risk (group 2) was established and the patient is alive with no recurrence.

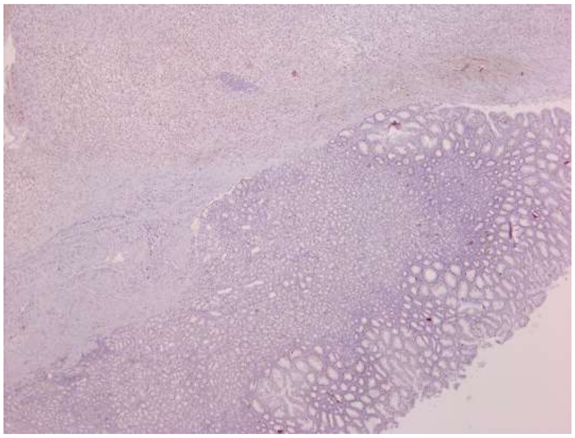
Figures case 3



HEx100



CD117x100



DOG1x100

Case no. 4

59 years old male with loss of appetite, abdominal pain, weight loss, is admitted to the hospital for investigations.

Esophagogastroduodenoscopy revealed an ulcerated tumoral proliferation on the body of the stomach and an ultrasound discovered multiple localized proliferations in left and right hepatic lobes.

A total gastrectomy was performed and the surgical specimen showed a12 cm white grey tumor with intramural development and cystic degeneration. On the microscopic examination it showed an epithelioid and spindle cell morphology with fascicles that intersect and intertwine at various angles, with more than 10 mitotic figures/50 hpf Immunohistochemistry showed negativity for CD117 and Desmin, and positivity for SMA and DOG1.

A diagnosis of GIST with high risk of recurrence (group 6b) was established and the patient survived time from the initial diagnosis was for 9 months.

DISSCUSSION

Arising in the interstitial cell of Cajal, GIST tumors are an entity dominated by mutations in KIT receptor tyrosine kinase which accounts for almost 80% of all cases. The histopathological diagnosis of such tumors is built upon the microscopic morphology and immunohistochemically stains.

The detection of CD117, a protein express by KIT gene, is essential for the diagnosis and we can find it in approximately 95% of GIST [8, 14].

Table 1: Clinical-pathological characteristics of the four cases presented

Case no.	Age	Location	Metastasis	Tumor diameter	Mitosis/ HPF	Cell type	Group	Death	Survival months	Resection
1	47	SI	no	4.0	<5	fusiform	2	no	84	R0
2	69	SI	peritoneum lung	8.5	<5	mixt	3a	yes	33	R1
3	67	S	no	3.0	<5	fusiform	2	no	135	R0
4	60	S	liver peritoneum	12.0	>5	mixt	6b	yes	9	R1

Table 2

	CD117	DOG1	Desmine	SMA
Clone Dilution	T595 1:40	K9 1:100	DE-R-11 1:100	αsm-1 1:50
Case no.1	negative	positive	negative	positive
Case no.2	Negative	positive	negative	negative
Case no.3	Negative	positive	negative	positive
Case no.4	negative	positive	negative	positive

However, there are 4-5% of GISTs that are negative for CD117 and in these cases immunomarkers like DOG1 (ANO1) are very useful for the confirmation of the diagnosis [9,15,16].

DOG1 shows higher prevalence of positivity in gastric epithelioid GISTs, which are often KIT negative.[17]

Depending of the antibody used, the positivity of DOG1 in KIT-negative GISTs varies: with clone DOG1.1, the positivity is 36% [18] and with clone K9, the positivity is 50–76%. [17,19]. We also used K9 clone in our cases, which we found very helpful.

Other immunohistochemical markers used, that can guide the diagnosis are CD34 (with a much higher positivity in the stomach-80% then in the small intestine-35%) together with SMA Desmin, Vimentin. CD34 was done only in one of our cases, a small intestine GIST and it was negative so the only reliable marker was DOG1.

Most of the GISTs are reported in the stomach (50-60%), jejunum and ileum (30-35%), duodenum (5%), colorectal (4%), and rarely in the esophagus and appendix (<1%) [10, 20]. Primary tumors outside the GI tract have been reported in small numbers in omentum [21,22], mesenteries and retroperitoneum [23,24]. The location of c-kit negative GIST is more frequently reported in the stomach [25, 26, 27] and less in the small intestine [28,29]. Two of our cases were located in the stomach but the other two located in the small intestine gave rise to diagnostic suspicion so we had to pay more attention at the differential diagnosis due to the rarity of the tumor site.

Location and size of the tumor influence the apparition of symptoms. Small tumors are usually silent and are being discovered incidentally during investigations or surgical procedures for other disease However if a GIST becomes symptomatic, it usually cause non-specific symptoms like weight loss, fatigue, nausea, bowel obstruction or overt or occult gastrointestinal bleeding due to mucosal ulceration or tumor rupture[30,9]. Two of our patients presented with nonspecific symptoms like abdominal pain, nausea, fatigue, weight loss, and the other two with bleeding signs. Non-specific symptoms delays the diagnosis and we can see from Table 1 that those two cases have also the largest diameter (8.5 cm in the small intestine and 12 cm in the stomach).

The prognosis and predictive factors for survival of patients with C-kit negative GISTs are still unclear and difficult to assess because of insufficient data. The tumor diameter, metastatic disease, incomplete resection is associated in our cases with a shorter survival rate (Table1).

DOG1 especially clone K9 is an invaluable marker of the diagnosis but mutational status comes in hand in the treatment management. Complete resection and inhibitors of tyrosine kinase are considered for the treatment as in c-kit positive GIST [31].

However when we encounter a c-kit negative GIST we need to take into consideration:
- The antibody that we use, the clone and the laboratory technique
- The fixation methods of the surgical specimen may influence the reaction
- The CD117 negativity does not exclude a GIST diagnosis and other markers like DOG1 are necessary to complete the immunohistochemical diagnostic panel; we also must think at GIST with other mutations like PDGFRA
- For a possible treatment with inhibitors of tyrosine kinase (imatinib) we must have in mind mutation analysis as well
- GIST wild type is a constantly changing concept, at first considered a KIT negative GIST, now is described as GIST with no identified gain of function mutation. Besides the KIT gene, GISTs may present mutations in another receptor tyrosine kinase - the PDGFRA which accounts for less than 10% of all GISTS [32].

According to most studies, activating mutations in KIT or PDGFRA are present in 85 - 90% and are mutually exclusive [33]. Other driver mutations studied, like BRAF, RAS, PIC3K, SDHA, NF1 need to have other genetic event in order to develop and progress [34,33, 35,36]

CONCLUSIONS

Kit negative GIST is a problematic entity which makes the diagnostic difficult.

In conclusion, we report four cases of CD117 negative, DOG1 positive GIST located in the stomach and small intestine, all being male patients.

It is important for the pathologists to beware of the fact that a CD117 negative in the context of a typical morphological appearance does not exclude a GIST tumor and also the oncologist must be aware not to exclude the therapy with imatinib based on the negativity of CD117.

Diagnostic predictability of using portal vein diameter in confirming portal hypertension

Varsha Somakumar[1], Cibi Manoharan[1], V.S. Srikanth[2], Rajesh Kannan[1], Chitra Tomy[1], Anagha Vasant[1], Vishal Marwaha[1], V.R. Mujeeb[2]

Abstract: *Objective: To find an accurate cut-off value for Portal vein diameter as a diagnostic tool for Portal hypertension on comparing with Doppler ultrasound, CT abdomen, or endoscopy of collateral circulation.*

Materials and methods: This was a cross-sectional study, with a sample size of 100 patients. Inclusion criteria were patients above the age of 15 years who underwent routine USG abdomen for various conditions in the Radiology Department of a tertiary hospital. Distribution of age, gender, chronic liver disease, portal hypertension, and portal vein diameter of all the patients were measured and recorded. Portal hypertension was diagnosed using the presence of collaterals either on upper endoscopy (if done), Doppler USG, or CT multiphase abdomen.

Results: Portal vein diameter of 10.5mm was found to have a sensitivity of 61.22%, specificity of 60.78%, a positive predictive value of 60.00%, a negative predictive value of 62.00%, and accuracy of 61.00%. 45 out of 59 (76.3%) and 37 out of 49 (75.5%) patients of the 50-70 years age group had chronic liver disease and portal hypertension respectively. 45 out of 65 (69.2%) males 37 out of 65 (56.9%) males developed CLD and PHTN.

Conclusion: Using portal vein diameter as a diagnostic indicator of PHTN has an accuracy of %, so it can be used in routine USG abdomen of CLD patients to prevent the dreaded complications of PHTN and treat it early. Male gender and patients above the fifth decade were increasingly predisposed to both CLD and PHTN.

Keywords: *portal hypertension, chronic liver disease, portal vein diameter, collateral circulation*

INTRODUCTION

Portal hypertension is defined as portal venous pressure more than 12 mm of Hg [1]. It is measured as the hepatic venous pressure gradient (difference of wedge hepatic pressure and free hepatic venous pressure), which is normally 4-6 mm Hg. More than 10 mmHg is portal hypertension, and more than 12 mmHg causes clinically significant variceal bleeding. [2]

Portal hypertension is major pathophysiology in patients with cirrhosis. Portal pressure is the gold standard to evaluate the severity of portal hypertension, and radiological intervention is the only procedure for pressure measurement [3].

Causes of portal hypertension are pre-sinusoidal (portal vein thrombosis, extrinsic compression of portal vein, Schistosomiasis (S. mansoni or S. japonicum)), sinusoidal (cirrhosis) and post-sinusoidal (Budd-Chiari syndrome, hepatic venous-occlusive disease, congestive cardiac failure) [1]

Portal hypertension leads to dilatation of portal vein,

splenomegaly, and formation of portal-systemic collaterals at different sites. The portal system and the systemic venous circulation are connected at several locations. Collaterals develop in areas where anatomic connections exist between the portal venous and systemic circulation. These are vascular channels that are functionally closed in normal conditions but become dilated in portal hypertension as a consequence of increased intravascular pressure and blood flow. These gastro-oesophageal varices are responsible for the main complications of portal hypertension and massive upper GI bleeding [4].

The complications of portal hypertension (gastrointestinal hemorrhage, hepatic encephalopathy, hepatorenal syndrome, and ascites) continue to be the cause of significant morbidity and mortality. Portal hypertension remains one of the most serious sequelae of chronic liver disease [2].

To prevent bleeding from occurring, an appropriate early diagnosis of oesophageal varices at risk of bleeding should be achieved. Upper digestive tract endoscopy is the gold-standard method for diagnosing the presence of gastroesophageal varices and identifying signs of risk of bleeding. Universal endoscopic screening of oesophageal varices was recommended in all patients newly diagnosed with cirrhosis until 2015. However, due to the increase in the proportion of patients with early cirrhosis achieved by non-invasive diagnostic methods, this strategy proved to lead to a large number of unnecessary endoscopies that would eventually decrease the patient's compliance and increase the health system costs. In the last 10 years, increasing evidence regarding non-invasive methods accumulated and proved useful for stratifying the risk of carrying varices and varices requiring treatment in patients with CLD [5].

60-80% of patients with cirrhosis of the liver are associated with esophageal varices and 25-30% of them have got a risk of bleeding. Every year incidence of esophageal varices increases by 5% and 5-10% of patients with small varices progress to large varices [6].

Endoscopy is the standard diagnostic approach in patients with portal hypertension. But it is an invasive technique. Noninvasive imaging techniques are preferred for early diagnosis and prevention of complications. Portal vein diameter, peak systolic velocity, presence of collaterals, splenomegaly, etc can be found using Doppler USG and CT multiphase abdomen. The overall sensitivity for detection of coronary-gastroesophageal collaterals using USG was 80% and 64%, respectively, in a study done by Subramanyam et al. [7]. Doppler USG is frequently obtained in patients with chronic liver disease, suspected portal hypertension, and known portal hypertension. Among the many findings of portal hypertension is the enlargement of the portal vein, decreased portal vein velocity, increased congestion index, development of portosystemic collaterals, and reversal of portal vein flow. Using all of these, it is possible to diagnose portal hypertension with a high degree of sensitivity and specificity non-invasively [8].

It is possible to rule out clinically significant portal hypertension in patients with cirrhosis (i.e., hepatic venous pressure gradient ≥ 10 mmHg) with a level of clinically acceptable accuracy by combining measurements of liver stiffness, spleen stiffness, and Doppler ultrasound evaluation. The combination of these methods allows for the identification of patients with the most serious degree of portal hypertension as seen by Bolognesi M et al. [9].

Despite the safety, affordability, and widespread use of ultrasound, there is a paucity of literature on ultrasonographic assessment of the portal vein (PV) diameter in adult patients in our local environment [10]. According to a study done by Nestaĭko OV [11], real-time ultrasound investigation could provide important information and should be used as a non-invasive and harmless investigation in hepatological studies. Splenic Stiffness can also be used for assessing and monitoring PHTN in hepatitis C induced cirrhosis according to the study by Colecchia et al. [12].

The cutoff point for portal vein diameter differs from study to study despite the existence of a normal mean portal vein diameter between 10–15 mm in different settings. This implies the existence of limited evidence on the exact portal vein diameter which can help diagnose portal hypertension early [13].

This study will help find an exact cutoff point of portal vein diameter which can help rule out false positives and find out false negatives and provide prompt detection and treatment and prevention of progression of a chronic liver disease patient to portal hypertension, using a routine non- invasive USG scan.

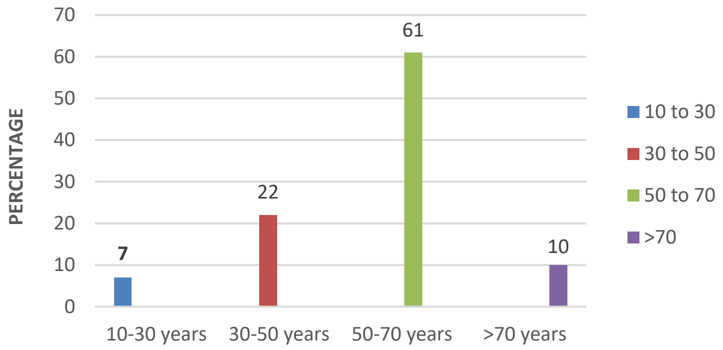
MATERIALS AND METHODS

This is a cross-sectional study carried out in the Radiology department of AIMS, Kochi. Since this is a pilot study, a total of 100 patients above the age of 15, referred from various other departments to the Department of Radiology for routine USG of the abdomen are included. Those patients who underwent imaging studies elsewhere, patients having thromboembolic problems, etc are excluded. Portal vein diameter and Doppler study of spleen for splenic collaterals are carried out. MRD numbers of these patients are collected to note down their age, history of CLD, Portal hypertension, and the presence of collaterals in the CT scan of the abdomen or upper endoscopy (if taken previously) is tabulated in MS Excel. The cut-off for Portal vein Diameter is found using Receiver Operator Characteristic Curve in SPSS. Qualitative variables are expressed as percentages and quantitative variables are expressed as mean with standard deviation. Informed consent was obtained from all the patients. The Ethics Committee of Amrita Institute of Medical Sciences has approved the study.

RESULTS

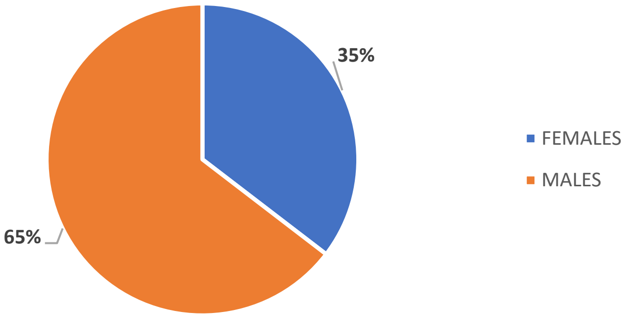
The mean age of the sample population was 54.9 +/- 13.89 years, median age 56 years (range of 17-84 years), and mode 67 years. The majority (61, 61%) of the patients were of the 50-70 years age group (Figure 1).

Figure 1: Distribution of age



35 (35%) of patients were females and 65 (65%) were males (Figure 2).

Figure 2: Distribution of gender



Of the 100 patients who underwent USG abdomen, 59 (59%) patients were found to have ultrasonographic features of chronic liver disease, while 41 (41%) patients did not have CLD.

49 (49%) patients were found to have collateral circulation, seen either on Doppler USG, or CT Multiphase abdomen, or Upper endoscopy (if done previously for any other indications), and 51 (51%) patients did not have any collaterals (Table 1).

Thus 49 (49%) patients had portal hypertension. Among the 50-70 years age group, 60.6% (37) of patients had PHTN, while 0 patients had PHTN in the 10-30 years age group, which clearly showed that PHTN was more common after the fifth decade of life (Figure 3).

Table 1: Distribution of portal hypertension (PHTN)

Collaterals	Frequency	Percent
Present	49	49.0
Absent	51	51.0
Total	100	100.0

More Males (56.9%) had PHTN as compared to females (34.2%), which was statistically significant, p-value <0.05 (Figure 4).

ROC curve to find out the portal vein diameter cut off had an Area 0.676, diameter 10.5 mm, with a sensitivity of 61.2%

and specificity of 60.8%, p-value of 0.002 (Figure 5).

Figure 3: Comparison of age and PHTN

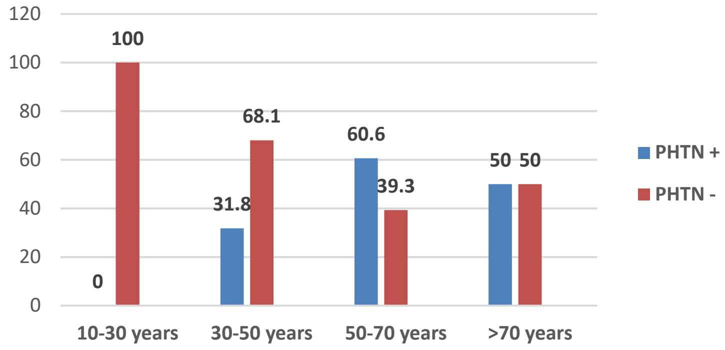


Figure 4: Comparison of gender and PHTN

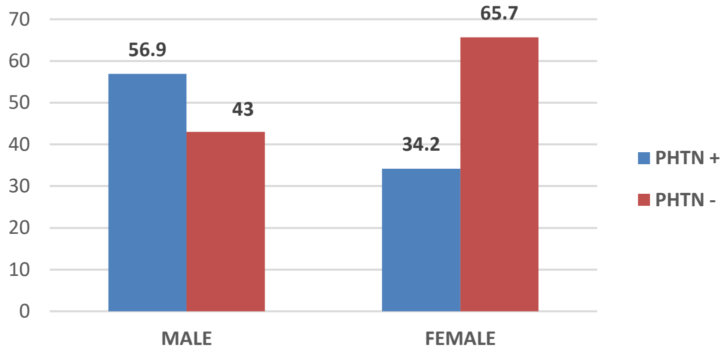

Figure 5: ROC curve of portal vein diameter and PHTN

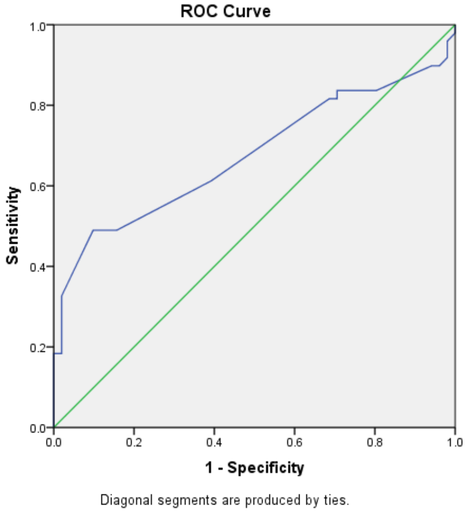

AUROC	0.676
PVD	10.5 mm
p value	*0.002*
Sensitivity	61.2%
Specificity	60.8%

DISCUSSION

Portal hypertension is the most common complication and also one of the important causes of death in chronic liver diseases. Increased resistance to portal blood flow due to alteration of the hepatic architecture leads to dilatation of portal vein, splenomegaly, and formation of oesophageal and gastric varices, variceal hemorrhage, ascites, hypersplenism, encephalopathy, etc [4]. The overall sensitivity for detection of coronary-gastroesophageal collaterals using USG was 80% and 64%, respectively, in a study done by Subramanyam et al. [7].

The mean age of the sample population was 54.9 +/- 13.89 years, the median age was 56 years (range of 17-84 years) and the mode of the age was 67 years. Most of the patients (61.0%) were in the 50-70 years age group, similar to the findings of Gaduputi et al. [14]. In a similar study done by Gunda et al. [15], it was found that the odds of having esophageal varices were independently higher among patients with increased age (Median age of 51 vs. 45 years; OR:1.02; 95%CI: 1.0–1.04; p = 0.030)

Out of the 100, 35 (35.0%) of patients were females and 65 (65.0%) were males. This pattern of male predominance is comparable to the study done by Sharma et al. [16] which had 86.1% of male patients. In the study by Akande et al. [17], 81% of males and a mean age of 44+12.6 years were seen among the cases.

More patients, i.e 73.7% and 60.6% of patients in the 50-70 years age group was found to have chronic liver disease and portal hypertension respectively; which clearly shows that both CLD and subsequently the development of PHTN is more common after the fifth decade of life. The same was the case with the male gender, i.e, 69.2% and 56.9% of males had CLD and PHTN respectively; which again shows that males have an increased association with CLD and subsequent development of PHTN. In a similar study done by Manik Mahajan et al. [18], it was found that the majority of the patients (32%) belonged to the 6th decade, with 66% of male and 34% of female patients having CLD and PHTN.

10.5 mm was found to be the cut off for Portal vein diameter in our study using ROC curve, with an area of 0.676, p-value 0.002, comparable to that found by Bhattarai S et al. [19], Sarwar et al. [20], and Guo et al. [21]. Collateral circulation was found in 49% of patients, which was seen either during Doppler ultrasound, CT multiphase abdomen, or endoscopy. Out of these 30, (60.0%) of the patients had a portal vein diameter of more than 10.5 mm. These were the true positive cases. Among these, 72% were in the 50-70 years age group. A similar study done by Gemecho et al. [13] revealed a normal mean portal vein diameter of 10.6 mm ±1.8 SD with a respirophasic variation of 25.6% and in the study by Ekta Gupta et al. [22] in North India, mean normal portal vein diameter measurement in male subjects was 10.33 mm ± 1.004 & in female 9.41 mm ± 1.16.

PVD > 10.5 mm was found in 20 (40.0%) of patients, but they did not have any collaterals; i.e these were the false-positive cases. CLD was found in 6 (30%) of these patients while 1 (0.5%) patient had portal vein thrombosis which explains the increase in diameter. Higher portal vein diameter was seen in those patients with esophageal varices in the study by Sangma MA [23] and Li FH et al. [24], as well as in cirrhotic children by Riahinezhad et al [25]. Diameter tended to increase in Child-Pugh scoring initially, before getting stenosed at higher scores, as found by Zhoy et al. [26].

The true negative cases were 31 (62.0%) of patients, who had a portal vein diameter less than 10.5 mm. The false-negative cases, i.e, 19 (38.0%) patients with PVD<10.5 mm but with the presence of collaterals, were long-standing chronic liver disease patients with well-established collateral circulation and a grossly shrunken liver, which led to the stenosis of the portal vein, leading to the decrease in PVD. Normal mean portal vein diameter in Ethiopian patients was found to be 10.0+1.8 mm (range 8.2 to 11.8) with a 21.5% reduction with the phases of respiration, in a similar study done by Scabel et al. [27]

In another study done by Lopamudra et al. [4], the average portal vein diameter of patients without gastro-oesophageal varices was 11.545 ± 1.514 mm and of patients with varices 13.998 ± 1.123 mm, which was slightly higher than the PVD found in our study, so was the normal mean portal vein diameter found in a study by Jefferey W et al. [28], which was 11 + 2 mm in patients aged between 21-40 years.

Thus, portal vein diameter of 10.5 mm had a sensitivity of 61.22%, specificity of 60.78%, the positive predictive value of 60.00%, the negative predictive value of 62.00%, and accuracy of 61.00%, in correctly diagnosing portal hypertension. In a similar study done by Johana Prihartini et al. [29], PVD of 11.5 mm had a sensitivity of 75% and a specificity of 54.5%. The sensitivity of using portal vein calibrations was found to be only 41.8% in the study done by Bolondi L et al. [30].

Limitations of our study: Portal vein diameter can vary in various physiological conditions, like inspiration, expiration, duration of liver pathology, etc. In our study, the diameter was taken at the hilum without taking into account the respiratory changes or the duration of CLD. Portal vein diameter can also vary according to age. There are wide variations in the age groups of the patients. More specific indicators like splenic size, peak systolic velocity, the direction of flow in the portal vein could have been included in the study.

CONCLUSIONS

Thus, portal vein diameter of 10.5 mm was the cut-off above which portal hypertension could develop, as was shown in the study. Though of limited sensitivity and specificity, it can be used to lookout for portal hypertension in chronic liver disease patients and prevent it as early as possible, before its dreaded complications set in. Both CLD and PHTN had a high incidence after the fifth decade of life, so screening for either disease is recommended after 50 years of age.

Diagnostic value of ultrasound in comparison with the pathologic results of fine-needle aspiration of thyroid nodules for rapid diagnosis of thyroid malignancies in patients referred to Baqiyatallah Hospital

Hojjatollah Khajehpour[1], Mohammad Ebrahimifar[2], Efat Naeimi[1], Mortaza Movahed[1]

Abstract: *Background and Aim: Various studies have reported that 4-7 percent of adults with palpable thyroid nodules that 50-70 percent of it's diagnosed with high-accuracy sonography. Although most thyroid nodules are non-cancerous and do not require treatment, a small percentage of them are associated with a potential risk of malignancy, which is an important early diagnosis by ultrasound or pathology. The present study aimed to compare the ultrasound with the pathologic results of fine-needle aspiration (FNA) of thyroid nodules for the rapid diagnosis of thyroid malignancies in patients referred to Baqiyatallah Hospital.*

Methods: The study population consisted of 100 (80 female, 20 male) patients with thyroid nodules in the age range of 19-82 years referred to the radiology ward of Baqiyatallah Hospital who were studied by the cross-sectional method. All patients were first scoring by ultrasound, then fine needle aspiration with thyroid nodule ultrasound was performed, and the specimens were referred to the pathology department for further evaluation.

Results: The pathologic results from fine-needle aspiration showed that only 8 of the 100 patients studied had malignant nodules that, by ultrasound scoring, 7 patients had 4 scores and 1 patient had 3 scores. However, the other 92 patients with benign nodules 57.60% of patients had score 1, 30.43% of patients had score 2 and 11.97% of patients had score 3.

Conclusion: According to the results of this study, it seems that ultrasound scoring is useful in the rapid diagnosis of thyroid nodules and prevent unnecessary thyroid nodule FNA.

Keywords: *fine needle aspiration, sonography, thyroid nodule, malignancy*

INTRODUCTION

The thyroid gland is one of the largest endocrine glands in the butterfly-shaped transverse section of the larynx. The units that make up the thyroid gland are a sinus or follicles, which are present in the central part of colloidal proteins as a source of thyroid hormone storage [1]. The thyroid gland has several key functions, such as iodine uptake and transfer, thyroglobulin secretion, iodine binding to thyroglobulin to make thyroid hormones, facilitating thyroid hormone secretion into the bloodstream, and interfering with body metabolism [2].

Thyroid hormones

Thyroglobulin, a large iodized glycoprotein, has been shown by researchers to be the first essential step in initiating the synthesis of thyroid hormones through iodine absorption through the food. Transmission of iodine to the thyroid gland occurs by binding to serum proteins, especially albumin, and

unbound iodine is often excreted in the urine [3]. TSH, which is secreted by the anterior pituitary cells, plays a central role in the control and evaluation of thyroid function, which is regulated by the TRH hypothalamic hormone [4]. Various studies have shown that there is an inverse relationship between thyroid hormone levels and basal TSH production, indicating the role of thyroid hormones as a major regulator of TSH production [5].

Common disorders of the thyroid gland include hypothyroidism, hyperthyroidism, goiter or enlargement of the thyroid gland, thyroid cyst, thyroiditis (Hashimoto's) and thyroid nodules. According to the latest studies, 7-8% of the world population has one of the thyroid disorders [6].

The term thyroid nodule refers to a group of thyroid cells that grow abnormally and fall into a mass, nodule, or node, which are divided into two groups of benign nodules and malignant nodules [7]. Various studies have shown that most thyroid nodules have non-cancerous and benign cells and various reports have estimated 1 in 10 patients as malignant nodules [8].

The types of thyroid nodules are divided into 3 groups of benign (colloidal), malignant (papillary) and suspicious nodules based on pathological findings. Among the types of nodules mentioned, only malignant nodules require further surgery and care.

Symptoms of patients with thyroid nodules include neck, jaw or ear pain, difficulty swallowing, itching or tingling in the throat, shortness of breath, sore throat, hoarseness, and most studies have reported that most patients Thyroid nodules are without symptoms and are often discovered during examination for other causes [9].

Researchers have identified chronic follicular thyroid nodule (Hashimoto's), congenital malformations such as failure to form a lobe, thyroid abscess, simple cyst, and non-thyroid diseases such as lymphoma and teratoma [10].

Tests for the diagnosis of thyroid nodules include measurement of thyroid hormone and thyroid-stimulating hormone, ultrasound, scanning, fine needle aspiration, and pathological examination (cellular aggregation) [12, 11].

Since a rapid diagnosis of malignancy facilitates the process of thyroid nodule healing, therefore, finding the fastest method of diagnosis is important for initiating therapeutic measures.

The present study aimed to compare the ultrasound report only with the pathologic results of fine-needle aspiration of thyroid nodules with the aim of rapid diagnosis of thyroid malignancies in patients referred to Baqiyatallah Hospital.

MATERIAL AND METHOD

Following the approval of the research plan by the University Research Council, informed written consent was obtained from patients' participation and distributed to those who referred to the thyroid nodule interventional ultrasound department and the indication of fine-needle aspiration. No entry and exit criteria were considered for the study.

Finally, 100 patients (80 females, 20 males) from thyroid nodules in the age range of 19-82 years referred to the radiology ward of Baqiyatallah Hospital and the statistical population were selected by census method and studied by the cross-sectional method. After obtaining biographies and demographic information by the student, patients were referred to a skilled sonographer for ultrasound (using Philips Affinity fog) and fine-needle aspiration (with ultrasound guidance) and the specimens were referred to the pathology department for cytological examination.

In thyroid ultrasound, tissue is examined for ultrasound by echogenicity and rate and extent of calcification. 6 modes of Hyper echo nodule (white nodule in ultrasound), Hypo echo nodule (gray and pale nodule in ultrasound), cystic nodule (absolutely Echoless), solid nodule (uniform echo), microcalcification (calcification less than 2 mm) and macro calcification (calcification greater than 2 mm) was determined by scanning ultrasound for scoring from 1-4. The four nodule states were hypo echo, solid, microcalcification, and a 1 cm-high scoring criteria of 1-4. Each of the above was given a score of 1 and the nodule with all four attributes scored 4. In fine needle aspiration, the thyroid tissue is sampled using a fine needle for the microscopic examination of existing cells.

Among the characteristics of malignant nodules can be severe porcelain, cell size and shape variation, dense and double or multilayered cell masses, etc. These features were reported by a skilled pathologist.

Data were analyzed by spss23 software.

RESULTS

The mean age of patients was 48.26±08/13 and the results of this study showed that malignant thyroid nodules were more prevalent in 40-49 years old patients and women in our study ($p<0.05$).

Of the 100 patients with thyroid nodules, 8 (8%) had malignant nodules, indicating that a thyroid nodule may be about 12 times more likely to be benign.

Ultrasound reports showed that of the 92 benign nodules, 58 were hyper echogenic, 22 were hypo echogenic, and 12 were cystic nodular, whereas of the 8 malignant nodules, 5 were hypo and 3 were iso- echogenic.

It was observed that the ratio of solid in malignant nodules was more than benign. The calcification rate in benign nodules was 17% for microcalcification and 2% for macro calcification, which was 40% and 20% for malignant nodules, respectively.

Pathologic reports showed 53 patients with nodular goiter, 28 with adenomatous goiter, 1 with a follicular lesion, 8 with papillary carcinoma, 8 with thyroiditis, and two remained unknown due to insufficient sample that both nodules were cystic.

Of the 8 patients with malignant nodules reported by the pathologist from the side of ultrasound, 7 (87.5%) cases had score 4 and one patient (12.5%) had score 3. While 57.60% of benign nodules had score 1, 30.43% had score 2 and 11.97% had score 3.

From the side of ultrasound scoring, 53 cases received score 1, 28 cases received score 2, 7 cases received score 3 and 12 cases received score 4. In terms of thyroid nodule count were 47 single nodules and 53 multinodular nodules.

From hormonal tests, 4 cases were hypothyroid, 5 were hyperthyroid and 91 cases were normal, 3 cases were hypothyroid or hyperthyroid, and 5 cases were normal. Eleven of the patients had a family history of thyroid disorders, which was found to be 5 out of 11 people and 3 in people with no history of malignancy.

DISCUSSIONS

This study aimed to compare ultrasound only report with pathologic results of fine-needle aspiration of thyroid nodules with the aim of rapid diagnosis of thyroid malignancies in patients referred to Baqiyatallah Hospital. The pathologic results of fine-needle aspiration in the present study showed that only 8 of the 100 patients studied had malignant nodules which, by ultrasound scoring, 7 cases had score 4 and 1 case had score 3. However, the other 92 patients with benign nodules 57.60% had score 1, 30.43% had score 2 and 11.97% had score 3. In other words, by taking into account the pathologic results in this study, it can be concluded that ultrasound results can be used as a quick tool in predicting thyroid nodule malignancy. The reason for the high success of sampling accuracy in this study was the use of ultrasound guidance during biopsy and slide preparation by the pathologist.

In 2015, Siyadati et al investigated the diagnostic value of fine-needle aspiration compared to pathologic results in the diagnosis of thyroid nodules in Babol Shahid Beheshti Hospital, northern Iran, for 22 years. The researchers said that fine-needle aspiration of the thyroid is a selective method of examining thyroid nodules that have recently been questioned in the management of nodules. This cross-sectional study was performed on cytology specimens of 225 patients who underwent thyroidectomy in Shahid Beheshti hospital of Babol for 22 years (1989-91). Age, sex, physician performing FNA, type, and surgical site, FNA and pathology results were recorded. Pathologic FNA results were classified into four groups of inadequate, benign, malignant and suspicious and pathologic results were also divided into two benign and malignant and compared. The results showed that in the diagnosis of malignant thyroid nodules, sensitivity was 60%, specificity 96%, positive predictive value 65%, negative predictive value 95% and diagnostic accuracy of 81.8%. Of the 225 cytological specimens, 127 were benign (56.4%), 47 suspicious (20.9%), 27 malignant (12%), and 24 inadequate (10.7%). Final pathology was also benign in 150 patients (66.7%) and malignant in 75 patients (33.3%). According to the results of this study, fine needle aspiration can be used to diagnose thyroid nodules [13].

Rosario et al., 2013 in Brazil, designed a study to predict malignancies in thyroid nodules with non-diagnostic cytology and to evaluate the value of ultrasound. The results of this study showed that in patients with thyroid nodules and repeatedly diagnosed cytology findings, ultrasound findings are an excellent parameter for choosing to continue their treatment, which would be useful for periodic ultrasound [14].

In a 2005 study in Taiwan, Lin et al., in the study of thyroid nodules by ultrasound and fine-needle aspiration, concluded that ultrasound combined with fine-needle aspiration detected 10 years earlier than other methods of malignancy [15].

In 2006, in Italy, Baratolata et al. designed a study entitled Quantitative and Qualitative Evaluation of Thyroid Nodule with Ultrasound Contrast. These researchers concluded that quantitative data corroborated the subjective findings and contrast ultrasound of the thyroid gland was a feasible procedure but found other random events during ultrasound may interfere and are one of the reasons limiting the potential of this method for the detection of thyroid nodules [16].

In 2009, Tramaloni et al. evaluated ultrasound and Doppler ultrasound and fine-needle aspiration in thyroid nodules. In this study, microcalcification, hypoechogenic nodules, and intra-nodular vascularization were introduced as criteria for malignancy [17]. In our study, as the grayscale ultrasound was used, therefore, vascularization was not used in malignant scoring.

Rago et al. 2008 evaluated ultrasound and Doppler ultrasound and fine-needle aspiration for malignant patterns in thyroid nodules. In this study, microcalcification, hypoechogenic nodules, and intravascular nodular vasculature were introduced as criteria for malignancy [18]. In our study, as the grayscale ultrasound was used, therefore, vascularization was not used in malignant scoring.

CONCLUSIONS

According to the results of the present study, it seems that ultrasound scanning alone is useful in the rapid diagnosis of thyroid nodules and to suggest a more accurate result, the present study should be designed in a larger statistical population. More accurate and desirable results can be performed on specific types of lesions. Thyroid nodules with scoring 3 and 4 should also be subjected to the fine-needle aspiration to facilitate faster and more accurate diagnosis and to prevent the progression of malignancy. Among the properties of the nodule used in scoring, nodule size alone may not be a good criterion for nodule malignancy, whereas solidity, hypo echogenic, and microcalcification favor the malignancy of the nodule, and can exclude nodules that score 1 or 2 can be tracked by ultrasound and does not necessarily need to be sampled.

CLINICAL PRACTICE

Differential diagnosis in case of overdose of antiepileptic treatment. Clinical case

Mihail S. Tudosie[2], Genica Caragea[1], Ana D. Radu[4], Ilenuţa L. Dănescu[3]

Abstract: *Acute drug-related acute intoxications or suicidal ideation following overdose with anticonvulsants may cause major morbidity, in many cases requiring intensive care and prolonged periods of hospitalization.*

The case of a 35-year-old patient known for a history of epilepsy with phenobarbital and carbamazepine treatment is brought to the Emergency Unit by transfer from another hospital in a comatose state with insufficient respiratory performance, bilateral active mydriasis. From the family members' claims, the patient discontinued treatment with phenobarbital two weeks ago. Following interdisciplinary examination, hospitalization in the Neurology Department with the diagnosis of epileptic status is decided. Due to the progressive aggravation of acute respiratory insufficiency, the ventilator support is constituted. Since the biological samples related to probability diagnosis and cerebral imaging were not conclusive, toxicological samples were collected. The GC/MS analytical toxicology screening in urine reveals the presence of carbamazepine and phenobarbital and their plasma levels (5.92 and 92.3 mg/l) as determined by the FPIA method indicate an overdose of phenobarbital therapy. The patient is taken over by the Department of Clinical Toxicology where specific intensive care measures are applied. Clinical evolution is favorable. The psychiatric examination highlights the depressive idea, suicidal ideas, and uselessness. The suicide attempt is confirmed. It also presents a review of the main information about acute poisoning with anticonvulsants, but also about the analytical laboratory methods that bring precious information in establishing the diagnosis of certainty.

Keywords: *phenobarbital, carbamazepine, GC/MS, urine, acute poisoning*

INTRODUCTION

Acute drug-related acute intoxications or suicidal ideation following overdose with anticonvulsants may cause major morbidity, in many cases requiring intensive care and prolonged periods of hospitalization. The evaluation and stabilization of the poisoned patient is similar to all cases presented at the Emergency Unit and aims at detecting vital risk disruptions and correcting them in the shortest possible time [1].

Phenobarbital ($C_{12}H_{12}N_2O_3$) is a drug of the barbiturates group used since 1912. It is generally administered to epileptic patients at doses of 60-200 mg/day, commonly in combination with other anticonvulsants [2]. In the chronic administration of 200 mg / day in epileptic patients, the concentrations had average values of 29 mg/l and 16-48 mg/l [3]. Plasma concentrations of 10-30 mg/l are generally considered appropriate for patients receiving phenobarbital as an anticonvulsant and may require 14-21 days to reach the level of equilibrium.

The compound had a plasma half-life of about 4 days [4]. Toxic reactions to phenobarbital at chronic doses occur at plasma concentrations exceeding 40 mg/l. Patients develop

coma with reflexes present at plasma concentrations of 65-117 mg/l and reflexes loss occurs at concentrations of 100-134 mg/l [5].

The mechanism of action of barbiturates and implicitly of phenobarbital is related to their affinity for the GABAA receptor, which is fixed in distinct sites with both benzodiazepines and GABA (the main CNS inhibitor neurotransmitter), potentiating its effect. Barbiturates also block a glutamate receptor - the major excitatory neurotransmitter in the CNS [6].

In acute intoxication with barbiturates, because of the depression of central respiratory control mechanisms, following a general depression and anxiety, death may occur in the absence of artificial ventilation and vital functions support measures. In short-duration barbiturates intoxication, the cardiopulmonary arrest may be the cause of premature death and late: circulatory insufficiency, cerebral edema, acute pulmonary edema. Central nervous effects are related to the severity of intoxication. Because there is no specific antidote, the goal of therapy remains to increase the elimination of toxic and support vital functions. In determining the establishment of measures to increase the elimination of anticonvulsants (hemodialysis, hemoperfusion, plasmapheresis), it is also important to measure the plasma levels of these substances in relation to the clinical condition of the patient.

Carbamazepine is a classic anticonvulsant, largely used, with an iminostilbene nucleus, similar to that of tricyclic antidepressants, with a prolonged digestive absorbtion time. Its mechanism of action is partially known, acting on the neuronal membrane towards stabilizing its hyperexcitability, inhibiting repetitive neuronal discharges and reducing excitatory synaptic transmission by blocking voltage-dependent sodium channels. The reduction is glutamate discharge and the stabilization of the neuronal membrane contribute only supplementary to the antiepiletic effect [7]. Its main metabolite is 10,11-carbamazepine epoxide, an essential metabolite which possesses the same toxic effects as the basic drug. In pharmacological doses, the distribution volume of carbamazepine is of 1.4 l/Kg, and the half-life is of 15 hours.

The absorbtion of carbamazepine occurs slowly, 65-85% of it binds to plasma proteins and it is quickly distributed to all tissues. The maximum serum levels are reached within 6 to 8 hours following ingestion and steady-state plasma concentrations, considered to be therapeutic levels of carbamazepine, considerably vary between individuals; for most patients, the therapeutic level of carbamazepine is between 4 and 12 ml//l and the concentration of the active metabolite (10,11 epoxide-carbamazepine) is 30% of the plasma levels of carbamazepine [7]. In epilepsy, carbamazepine is administered in doses of 0.8 to 1.2 g / day, 2-3 times a day for an adult and 0.1-1 g / day (10-25 mg / kg / day) for children of ages from 1 to 15. Therapeutic doses can be optimized through therapeutic monitoring (TDM) due to a good correlation between plasma levels and the therapeutic effect [8]. As it is an enzymatic inducer, carbamazepine can induce its own metabolism, this phenomenon being responsible for the reduction of its half-life over repeated administrations.

In case of carbamazepine overdose, many of the observed effects can be tied to secondary mechanisms of its tricyclic structure. The symptomatology of an acute intoxication is characterized by coma, pyramidal signs, nausea/vomiting, hypotension, hypothermia, anticholinergic symptomatology (tachycardia, mydriasis, redness, urinary retention etc.) tremor, convulsions, respiratory depression, cyanosis, sinusal bradycardia or atrio-ventricular conduction disorders [9]. Plasma levvels of carbamazepine between 18-70 µg/ml have been measured in carbamazepine overdoses, while levels higher than 40 µg/ml have been associated with an increased risk of complications such as coma, convulsions, respiratory insufficiency, and cardiac conduction disorders [10].

CASE PRESENTATION

A.G, female gender, 35 years old, admitted for being comatose, with acute respiratory insufficiency and non-reactive bilateral mydriasis.

Personal medical history – known to have had previous comitial crises, treated with phenobarbital and carbamazepine

History – Comitial patient, brough from the Emergency Admission Unit in a coma, transferred from another hospital. From her family's affirmations, the patient had stopped taking phenobarbital 2 weeks before.

Interdisciplinary consults performed in the Major Emergency Department:

- neurosurgical consult: coma GCS = 5 points, no neurological signs;
- internal diseases consult: PA = 100 mmHg, AV = 76 b/min, ECG sinusal rhythm with no pathological alterations.

CT scan: no heterodense lesions are present at brain level, ventricular system situated on median line.

The patient is taken over by the Neurology Department with a diagnosis of epilepsy.

Objective examination upon admission: second degree coma; non-reactive; oro-tracheal tube, spontaneously breathes through the tube; TA = 120/70 mmHg, AV = 85 b/min; gastric statis = 200 ml; diuresis = 400 ml; positive bilateral Babinski bilateral; fixed mydriasis, pupil OD>OS, fixed eyeballs; no meningeal signs; spontaneously and discreetely mobilizes right superior limb. Due to the progressively aggraveted acute respiratory insufficiency, mechanical ventilation is applied (BIPAP, PEEP = 5 mbar, FiO2 = 40%, Pmax = 19 mbar);

In order to confirm the diagnosis, lumbar punction was performed and probes of cerebrospinal fluid were sent for biochemstry, bacteriology and cellularity.

A central subclavicular catheter was also applied.

The pulmonary radiography does not show evolving pleuro-pulmonary changes.

As the diagnosis could not be confirmed by the biological samples, toxicological samples were taken. The GC/MS examination of the urine shows the presence of carbamazepine and phenobarbital.

Biological table: biochemistry, hematology, coagulation within normal limits.

The patient is taken over by the Clinical Toxicology Department.

Intensive therapy measures: ventilation support; ensuring permeability of respiratory pathways – aspiration of tracheo-bronchial secretions through the IOT probe; naso-gastric drainage tube; hydro-electrolytic rebalancing; plasmatic and urinary alkalinization under paraclinical control (EAB).

Support therapy: monitoring of vital functions; ventilatory support; hemodynamic monitoring; diuresis monitoring; analytical control of urine.

Clinical evolution is favorable – the patient becomes conscious, reacts to stimuli; shows spontaneous breathing signs; is detubed and restarts spontaneously breathing. Physical recovery measures continue.

Psychiatric exam reveals depressive ideation, suicidal ideas and ideas of uselessness. A suicide attempt is confirmed.

She is tranferred to the specialized psychiatry clinic.

Analytical diagnosis of certainty in case of acute drug intoxication

One of the most used methods in identifying the substances incriminated in acute drug intoxications is gas chromatography - GC coupled with mass spectrometry - MS. Thus, by gas chromatograph injection of a completely unknown matrix, if the working conditions are well chosen, at the exit of the GC they will be placed in turn at the detector's disposal. If the detector is of the MS type and the injection matrix contains organic substances whose molecular weight falls within the working range of the mass filter, it will determine the mass spectrum for each substrate. In our case, the urine sample collected from the patient is follows to the liquid-liquid analytical procedure and injected into the GC/MS system, with ion trape detection, electronic ionisation 70eV. Midazolam is used as an internal standard. The method chosen for the separation and qualitative identification of analytes by GC / MS is called medicamente.mth, with a 45-minute acquisition time. Upon completion of the acquisition program, read the total recorded chromatogram. Apply the background correction and then proceed to the identification of each chromatographic peak. It establishes the mass spectrum that corresponds to it and these spectra are automatically compared with the existing spectra in the laboratory database. The database includes specialized spectral libraries (Nist98, PMW, Wiley6).

The temperature program used was:

- temperature injector: 280 ° C,

- for column oven: Start at 1400C, 2 minute range, increase temperature by 5° C / min to 290° C, 13 minutes (total time 45 minutes).

Following these investigations, the result is established. In our case, we separated the chromatographic column and identified the following substances: Phenobarbital and carbamazepine at the retention times shown in Table 1, based on the mass spectrum obtained by EI.

Table 1: Data on identified compounds (molecular weight, retention times and characteristic spectral lines m/z)

Compound	MW (g/mol)	Retention time (min)	CAS. No.	Spectral lines (m/z)
Phenobarbital	232	16.001	50-06-6	117, 204, 231
Carbamazepine	236	16,944	298-46-4	193, 236
Midazolam (SI)	326	26,951	59467-70-8	310, 327

In case of acute drug intoxications, measuring plasma levels is important both to establish the seriousness of the intoxication and to monitor the efficiency of the medical treatment.

Therapeutic drug monitoring is performed based on the principle of fluorescent light polarization on a Cobas Integra 400/800 system for serum samples taken from patients. It is a quantitative method which uses the the fluorescence of substances and is based on immunological properties (antigen- antibody) of the analyzed substances. The principle of this method is based on exciting the sample with a fixed wavelength and measuring the quantity of light emitted by a substance called a luminophore, on another wavelength. The specific antigens, present in the tracer, bind to the antibodies present in the sample [11]. Thus, the quantity of light emitted by the sample will be inversely proportionate to the quantity of searched substance.

Std- 1	Assign.	Calc.	Rate
RM:	20.00 mg/l	20.00	131.717 mP
☑ R1:		20.00	131.710 mP
☑ R2:		20.00	131.724 mP

In this case, determinations of the plasma levels of carbamazepine and phenobarbital in the samples were performed using the FPIA method, which implies determinations on a calibration curve in 6 points. The quality control is performed for three known concentrations.

The plasma concentration of carbamazepine on the first and second day of hospitalization was 5.92 and 2.90 mg/L, respectively. Because this value falls within the therapeutic limit, no measurements have been made during hospitalization. In contrast, the plasma level of phenorbarbital was increased and its variation in the first 7 days of hospitalization is shown in Figure 3.

CONCLUSIONS

Antiepileptic treatment based on selective anticonvulsant medication (carbamazepine and phenobarbital) follows the avoidance and treatment of epilepsy seizures, and at therapeutic doses these crises stop. Unfortunately, cases of overdose of treatment may occur either accidentally or for a suicidal purpose.

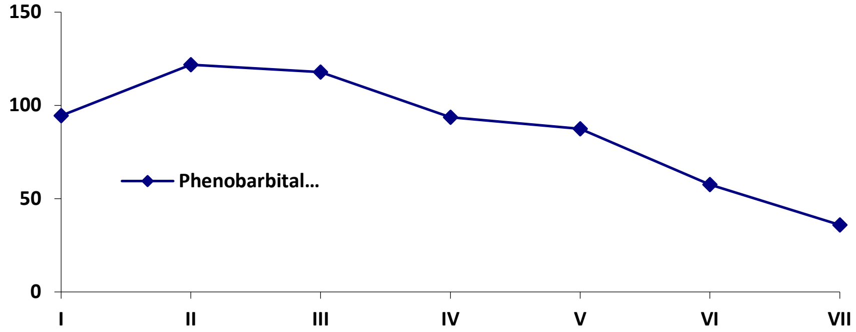
In the case presented, the crisis appeared could be interpreted in a double context, in the absence of correct anamnestic data, either in the case of baseline, in the absence of anticonvulsant treatment or in the case of overdosing of the medication.

Table 2: The therapeutic and toxic plasma levels for phenobarbital and carbamazepine (The Cobas Integra 400+ System)

Compound	Therapeutic levels (mg/L)	Toxic levels (mg/L)
Phenobarbital	10-30	>40
Carbamazepine	4-8 (associated with other anticonvulsants) 6-12 (unique treatment)	>8 >12

Compound	*Plasma levels (mg/L)*						
	I	**II**	**III**	**IV**	**V**	**VI**	**VII**
Phenobarbital	94.5	121.8	117.9	93.7	87.4	57.6	35.9
Carbamazepine	5.92	2.90					

Figure 3: Plasma levels of phenobarbital during the first 7 days of hospitalization



In establishing the differential diagnosis of certainty, toxicological screening of biological products was of great importance, both by identifying drug substances in the urine (by the GC/MS method), especially by measuring their plasma levels by the FPIA (Fluorescence Polarization Immunoassay). Measuring plasma levels of some drugs facilitates the optimization of therapeutic behavior but also reduces the toxic effects of these drugs in case of overdose

Digital techniques for anterior teeth form selection in complete edentulism

Ana Maria C. Țâncu[1], Elena Preoteasa[1], Ștefan Popa[2], Cristina T. Preoteasa[1], Mihaela Pantea[1], Mihaela Tănase[1], Marina Imre[1]

Abstract: *The aim of this study was to compare two computerized digital esthetic design methods (DSD and Visagismile) in order to properly choose the appropriate form of the maxillary frontal teeth for complete bimaxillary edentulous patients and to validate the use of these applications in complete edentulism. An online questionnaire was submitted to a group of 100 persons (dental doctors, dental medicine students and persons activating in other fields); the respective persons were requested to choose the form of maxillary frontal teeth for a group of four complete bimaxillary edentulous patients, whose esthetic design had been performed by using the two computerized progams. Following the respondents' analysis of the esthetic previews elaborated for the four patients 60% of the total answers were in favour of DSD while the remaining 40% were in favour of Visagismile; these percentages are identical with the ones obtained on the basis of the answers given by dental doctors and dental medicine students. In case of the respondents activating in other fields the percentages were 66% in favour of DSD and 34% in favour of Visagismile. Based on the results of the study the two computerized methods were validated also for cases of complete edentulism but further studies to confirm this validation are still required. These two methods improve the dental doctor/patient communication and certainly provide a higher predictability of the esthetic results of prosthetic restorations not only for dentate patients but also in cases of complete edentulism.*

Keywords: *esthetic preview, complete edentulism, DSD, Visagismile*

INTRODUCTION

Choosing the most appropriate form for maxillary frontal teeth has always represented a challenge in the prosthetic restorations of complete edentulism as doctors had available a limited number of parameters (facial profile, sex, age, personality), which were often subjective methods of analysis and, as a consequence, the esthetic results had a low degree of predictability. [1].

Modern dental medicine uses digital technologies also in the field of dental esthetics, thus ensuring that the esthetic results of the prosthetic restorations meet as many requirements as possible having, at the same time, a high degree of predictability, given the possibility to preview the results.

A considerable number of such digital applications for smile simulation have been developed, among which: DSD App, VisagiSmile, Photoshop CS6, Keynote, Planmeca Romexis Smile Design, Cerec SW 4.2, Aesthetic Digital Smile Design, Smile Designer Pro [2].

[1] Faculty of Dental Medicine, "Carol Davila" University of Medicine and Pharmacy, Bucharest

[2] Private Practice, Bucharest

Smile planning applications adjust the digital technology to the smile design process. They can be used as multi-use conceptual tools, diagnosis and treatment plan preview instruments and can facilitate the communication with the patient and the dental technician, enhancing the predictability of the final results and allowing a thorough analysis of the facial and dental features otherwise superficially evaluated through clinical diagnosis, photographic assessment or by using models [3]. Among the esthetic software programs used at present in dentistry Visagismile and DSD are considered to be the most powerful tools in assessing and modifying the design of deficient smiles. [4].

Apart from the well-known DSD (Digital Smile Design) concept a new one, Visagismile, has been developed in the last years starting from the Hippocratic four types of temperament (sanguine, choleric, phlegmatic and melancholy) and the Jungian archetypes and symbols (basic geometric shapes and primary and secondary colours) [5]. The artist Philipp Halawell explained and developed the Visagism concept, which implies the creation of an image expressing a person's (patient's) type of personality, concept that has been integrated in the dental medicine, thus obtaining a teeth form that ensures a correlation between dental-facial harmony and the personality type [3].

The Visagism concept analyzes the relation between the facial features, temperament and patient's harmonious teeth configuration. The concept has been developed in the last years and validated for a large number of clinical cases (over 800). The software program is user-friendly, the doctor uploading one standard photography of the patient on the application, where it will be calibrated and the points composing the facial map of the patient will be selected. Based on the facial map and one brief psychological questionnaire (named "personality interview") filled in by the patient the application will establish the patient's temperament and appropriate teeth design. Afterwards the doctor can edit the dental configuration and superpose it on the patient's teeth in the photography so that the patient can preview the esthetic aspect to be obtained at the end of the treatment. All details related to the future teeth will be sent to the laboratory directly from the application in order to obtain the final prosthetic restoration [6].

We identified a large number of studies regarding the application of the esthetic software programs on dentate patients while the number of studies regarding the application of these programs on edentulous patients is quite limited. Starting from this finding we applied the two digital methods for choosing the form of the maxillary frontal teeth to complete edentulous patients.

The purpose of our work is to establish which of the two computerized methods used for choosing the form of the maxillary frontal teeth is more appropriate in case of complet edentulism.

MATERIALS AND METHODS

We performed a comparative study on a group of four patients of the Complete Denture Department of the Faculty of Dental Medicine within the University of Medicine and Pharmacy, "Carol Davila", Bucharest, Romania.

We used the following criteria for including the patients in the studied group: complete bimaxillary edentulous patients (both with and without dentures) and patients who gave their consent for participating in the studied group and for being photographed. The criteria for excluding the patients from the studied group were: dentate patients and non-cooperating patients.

For each patient a full set of photographs was taken, according to the protocols of the two software programs and all the data and photographs thus obtained were loaded and processed using Visagismile, DSD Keynote and Microsoft Excel programs. Previews of the form of the future artificial frontal teeth were obtained for each patient using both software programs; in achiving these previews, different steps were followed, as described in Table 1.

The ideal digital form of the future artificial maxillary frontal teeth was achieved for each of the four patients of the studied group by using the two computerized programs.

Table 1. Comparison between the steps for obtaining the previews corresponding to DSD Keynote and Visagismile programs

Keynote DSD	Visagismile
- Load the photograph on the software program and position the photograph in accordance to the calibrating lines - Draw the smile line and the mesio-distal limits of the future frontal teeth - Choose the forms of standard teeth that are preset by the program - Selection of the best fitting teeth-form by the doctor together with the patient - classical criteria for selection are taken into consideration (reversed face, age, sex, personality etc.)	- Load the photograph on the software program - ”Auto face reading” command performs the automatic calibration - The facial map results automatically by joining 27 facial points and a “facial type” is obtained, according to the four types of temperament (choleric, sanguine, melancholy, flegmatic) - The patient is subjected to the psychological test (a short interview consisting of four questions) - The software automatically ranks the facial type in percentages depending on the statistical parameters of the facial map and the results of the interview - Patient’s preferences as well as design related information can be inserted in the program in order to be submitted to the laboratory - Based on all the information inserted so far the program proposes a teeth design

In order to comparatively evaluate the two computerized methods used for choosing the form of maxillary frontal teeth with the aim of establishing which one is more appropriate for patients with complete edentulism, we submitted a questionnaire to a number of 100 persons. Out of 100 submitted questionnaires, 2 were considered invalid and 98 valid; the 98 persons were represented by 12 dental doctors, 53 students at the Faculty of Dental Medicine and 33 persons activating outside the medical field. This self-administered questionnaire (SAQ) included several questions and the two previews generated by the software programs (Figure 1), allowing us to receive feedback regarding the results obtained by using the two computerized methods from persons both activating in the dental medical field and outside the medical field. The questionnaire was filled in under the anonymity protection as the persons included in the study were not requested to provide personal information such as surname, name or personal identification number.

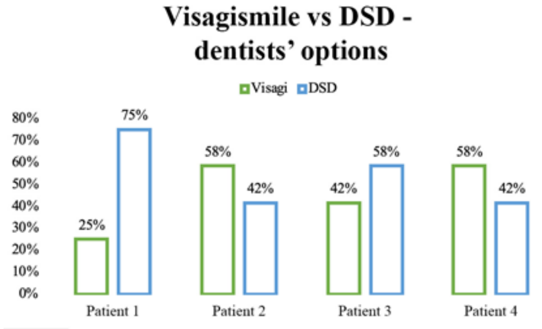
The questionnaire consisted of eight questions, of which the first four (closed-ended questions) regarded directly the four patients of the studied group while the remaining four were open-ended questions, referring to general information. The questionnaire, which was elaborated using Google Forms, was filled in online and it took sixteen days to receive all the answers. The information resulting from the answers to the questionnaires was further used, by employing Microsoft Office Excell 2018, to create statistical bases.

RESULTS

The results obtained after the questionnaire was filled in by the three categories of respondents are presented below:

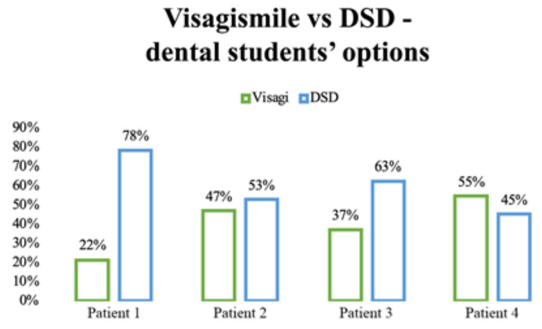
- Dental doctors opted for DSD in proportion of 60% while 40% were in favour of Visagismile (Figure 2);

Figure 2. Options expressed by dentists



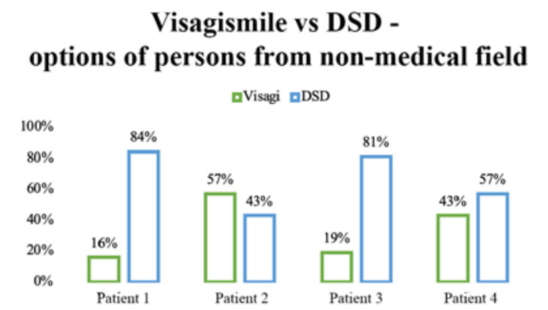
- Dental students were in favour of DSD in proportion of 60% while 40% chose Visagismile (Figure 3);

Figure 3. Options expressed by dental students



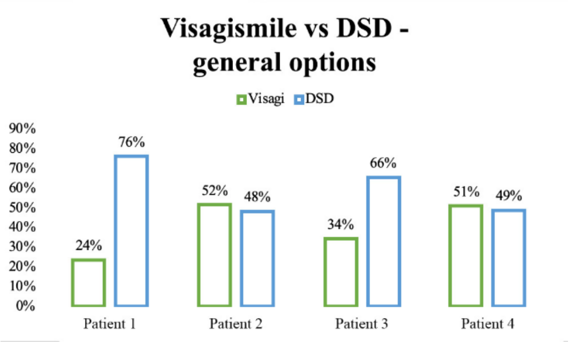
- The persons activating in non-medical fields were in favour of DSD in proportion of 66% while 34% opted for Visagismile (Figure 4).

Figure 4. Options expressed by persons from non medical field



At the level of the whole group of respondents included in the study 60% opted for DSD while 40% were in favour of Visagismile (Figure 5).

Figure 5. General options



DISCUSSIONS

There are still insufficient articles and studies illustrating the use of the smile planning digital applications to patients with complete edentulism. The modern smile design techniques are more effectively controlled through data collection and different digital smile design tools, contributing to all treatment steps up to the fabrication of the definitive restorations, either fixed or removable. Utilizing these digital tools together with classical treatment-planning rules and principles facilitates a controlled and predictable therapy when redesigning a smile [8] both for dentate patients and for complete edentulism cases.

Visagismile concept supports both dentists and patients in deciding about the aesthetics of the final prosthetic restoration and it is mostly applied for dentate patients. Using a specific protocol, a smile design that corresponds to individual facial features, temperament and personal preferences of the patient can be achieved [7, 8]. This application can also facilitate to a great extent the conception of the complete denture design by allowing the preview of the final result and the choice of the form, colour, size and arrangement of artificial teeth depending on the facial typology and the desire of the patient, who is directly involved in elaborating the treatment plan.

In modern dentistry DSD programs are also successfully used as tools for diagnosis, treatment plan visualization and communication with the patient and the technician; all these elements can improve treatment outcome predictability. As regards the characteristics of the 3D functions, CAD/CAM connectivity and practicality, the DSD application proves to be even more performant than Visagismile. However, not all the DSD programs available today provide the same competency for the comprehensive analysis of the dentofacial esthetic parameters [8]. As in the case of complete edentulism, the actual DSD techniques can be used with certain limitations related to the following facts: dynamics of the lips when smiling; shooting of the initial photographs, which requires a good stability of the dentures; the wax occlusion rims that do not fit all the facial typologies. At the same time, the preview of the final prothestic result obtained by applying DSD offers the complete edentulous patient the possibility of having a realistic view on certain aspects related to teeth form, colour and size, which are not correlated with his/her age and facial typology.

On the other hand, the ability of the digital planning programs to perform an appropriate esthetic analysis is evaluated also depending on the number of the dental-facial esthetic parameters used. Thus, if Visagismile has the advantage of using additional elements related to the patient temperament, DSD uses more dental-facial esthetic parameters. [2] This could be the reason why the majority (between 60% and 66%) of the respondents to our questionnaire expressed their option for the DSD method.

CONCLUSIONS

Dental esthetics is a topical though subjective field and the techniques used for choosing the maxillary frontal teeth, either classical or modern (digital), have particular elements and, as a consequence, our study is a subjective one, based on the opinions expressed by the three categories of respondents.

DSD and Visagismile programs have proved their usefulness for dentate patients and our study could contribute to demonstrating their effectiveness also in case of complete bimaxillary edentulous patients. However, future studies of higher complexity and performed on larger groups of patients are necessary in order to validate the application of such programs in cases of complete edentulism.

Drug allergies interpretation based on patient's history alone may have therapeutic consequences in hospital setting

Polliana M. Leru[1,2], Andreea Leontescu[3], Ion Stefan[1,4], Irena Nedelea[5], Iuliana Ceausu[6], Edu Antoine[1,3]

Abstract: *Background and aim. Adverse drug reactions (ADRs) are common events in medical practice, representing a matter of concern for both outpatient and in hospital care. Understanding and management of ADRs depend on their mechanism and clinical picture, which are complex and highly heterogeneous. Drug hypersensitivity reactions (DHRs) are immunologically-mediated ADRs, which are considered allergies after demonstrating evidence of either drug-specific antibodies or T-cells. The correct diagnosis of a drug allergy in hospital setting is essential for the outcome of treated disease and for the patient future in terms of therapeutic needs. Patients may be labeled as being drug allergic, based on their history and vague symptoms that do not correspond to a true allergic reaction. The aim of our study was to evaluate consequences of drug allergy labelling of female patients hospitalized in the department of obstetrics and gynecology from a university hospital during one year, in terms of medical attitude and therapeutic approach.*

Method and Results. We found that 159 out of 2395 patients hospitalized in the obstetrics-gynecology department declared a history of drug allergy on admission, but only 3 patients had medical documents and adequate recommendations from the allergist. Hospital medical attitude was significantly influenced in all declared allergic patients, mainly in terms of antimicrobial and anti-inflammatory therapy.

Conclusion. We concluded that overestimation of drug allergies in hospital care has important consequences in terms of current and future recommended therapy that should be based on standardized allergist evaluation.

Keywords: *drug allergies, hospital setting, patient's history, therapeutic errors*

INTRODUCTION

Adverse drug reactions (ADRs) are common events in medical practice, representing a matter of concern for both outpatient and in hospital care. The ADRs definition accepted by the World Health Organization is any noxious and unintended response to a medication that occurs at normal doses used for prophylaxis, diagnosis and/or treatment [1]. ADRs severity range from minor common side effects to potentially life-threatening medical conditions. The reported incidence of ADRs in general population varies between countries and may account for 2-3 % of all hospital admissions in some regions, as reported from Australia [2]. No reliable data about incidence of ADRs in Romania could be found. Understanding and management of ADRs depend on their mechanism and clinical picture, which are complex and highly heterogeneous [3].

The pharmacological classification of ADRs includes two major subtypes: type A which are dose-dependent and predictable reactions, with non-immunological mechanism,

[6] Ioan Cantacuzino Clinical Hospital, Bucharest

commonly termed intolerance and type B, which are unpredictable, not dose-dependent and have immunologic mechanism [4]. Drug hypersensitivity reactions (DHRs) are immunologically-mediated ADRs, considered allergies after demonstrating evidence of either drug-specific antibodies or T-cells [5]. Therefore it is recommended to use the term allergy only to describe reactions for which an immunological mechanism has been demonstrated. The majority of ADRs (>85%) are type A, while drug allergies comprise up to 15 % of ADRs [4]. It is considered that drug allergies affect more than 7 % of the general population [6]. The correct classification of an adverse drug reaction, by medical professionals, as allergy (due to immunological mechanism) or intolerance (non-immunological mechanism) has important medical implications [3]. Both underdiagnosis, due to underreporting and overdiagnosis, due to an overuse of the term „allergy" are common. There are still many controversies in drug allergy and recognized need for standardized and improved approaches of patients who report prior drug allergy [7]. Mislabeling of a drug allergy in patients records may result in unnecessary avoidance of an effective drug and medical recommendation of a second-line therapy, possibly less effective or more expensive. This situation is more frequent in case of antimicrobial drugs and may be also responsible for increased bacterial resistance to frequently used antimicrobials. Despite lack of reliable evidence, if an allergy label is noted into a patient medical record, it will remain for the rest of his life in most of the cases [8]. Maintaining the diagnosis of a drug allergy in hospital setting is essential for the outcome of treated disease and for the patient future in terms of therapeutic needs.

The aim of our study was to evaluate medical recording and consequences of drug allergy labeling of female patients hospitalized in the department of Obstetrics and Gynecology from a university hospital during one year, mainly in terms of current medical attitude, clinical outcome and therapeutic approach.

MATERIAL AND METHOD

We performed a retrospective analysis of hospital data over one-year period and we recorded diagnosis of drug allergies based on patient's history, as well as medical events considered as drug allergy and medical therapeutic attitude during hospitalization.

A total number of 2,395 female patients have been hospitalized during twelve months between January-December 2016 in the Obstetrics-Gynecology department of Nicolae Malaxa Clinical Hospital from Bucharest, with 1,817 patients hospitalized for childbirth and 578 patients hospitalized for gynecological diseases.

Patients were aged between 18-67 years, with a mean age of 33 years and about 80% lived in urban area. We recorded medical history documented in the patient file, including any type of reported drug allergies, written information regarding diagnosis confirmation and tolerated medication, concomitant diseases, other personal or familial allergies, current illness and medication, outcome and status at hospital discharge, particular recommendations regarding drug allergies. In cases who had medical events considered drug allergies during hospitalization, we noted type of reaction, severity, the possible culprit drug, relevant laboratory tests, therapeutic attitude and outcome.

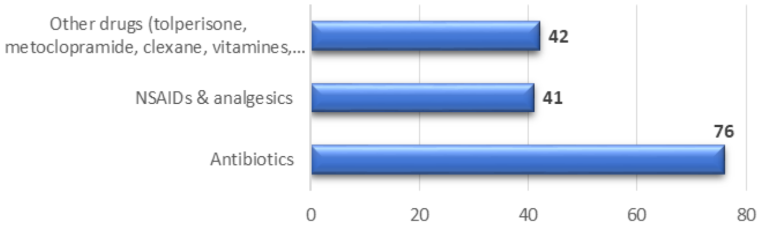
RESULTS

We found that 159 out of 2395 patients, meaning 6.63% of female patients hospitalized in the Obstetrics-Gynecology department declared a history of drug allergy on admission. From this group, 116 were pregnant patients hospitalized for childbirth and 43 patients were hospitalized for gynecologic diseases.

We noticed that 26 patients out of 159 (16.35%) were current smokers. The possible culprit drugs based on patient's declaration were: antibiotics in 76 patients (47.79%), non-steroidal anti-inflammatory drugs (NSAIDs) and analgesics in 41 patients (25.78%) and other drug allergies in 42 patients (26.41%) (Figure 1).

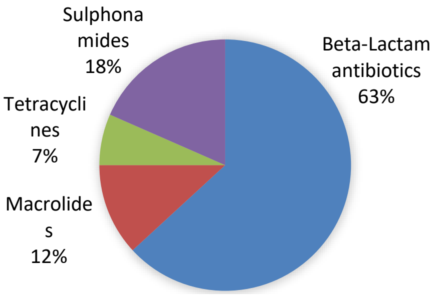
Only three patients out of 159 (1.88%) could show medical documents with diagnosis confirmation of drug allergy and clear recommendations to follow in case of future events.

Figure 1. Culprit drugs based on patient's declaration



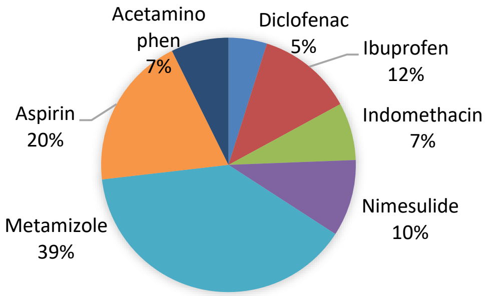
Clinical episodes considered drug allergies were recorded during hospitalization in another 9 patients from the total 2395 hospitalized group (0.37%), who have not declare any drug allergy on hospital admission. Eight patients had acute urticaria and one patient had respiratory symptoms. All these events have been successfully treated with antihistamines and systemic corticosteroids, based on allergist recommendation and resolved within short time. In all cases who declared history of drug allergy, the possible culprit drug was not administered and medication from another pharmacological class was considered. No allergological work-up could be performed during hospitalization, but this was recommended after hospital discharge. From the 76 cases who declared allergies to antibiotics, the incriminated classes were: beta-lactam antibiotics in 48 cases, macrolides in 9 cases, tetracyclines in 5, sulphonamides in 14 cases (Figure 2). The recommended antimicrobial therapy during hospitalization was quinolone in all cases (ciprofloxacin and levofloxacine).

Figure 2. Antimicrobials reported as culprit drugs



From the 41 cases who reported allergies to non-steroidal anti-inflamatory drugs (NSAIDs) and analgesics, the incriminated substances were: metamizole in 16 cases, aspirin in 8, acetaminophen in 3, diclofenac in 2, ibuprofen in 5, indomethacin in 3, nimesulide in 4 cases. (Figure 3)

Figure 3. NSAIDs and analgesics reported as culprit drugs



Other possible culprit drugs reported by patients who considered themselves to have drug allergies were: tolperisone, metoclopramide, clexane, vitamines, ergometrine, drotaverine.

The possible offending drug was avoided in all cases who reported drug allergies. No medical events attributable to anesthetics have been recorded.

In case of patients who declared allergy to NSAIDs, no drug from this class was administered, but also analgesics and antipyretics were avoided. No data referring to influence of drug allergy on duration of hospital stay could be found.

DISCUSSION

Our study showed that drug allergy is overestimated in hospital setting, based on patient's history alone and most of the patients have no evaluation or diagnosis confirmation from allergist. Hospital data referring to possible allergy were limited and some laboratory tests that might support atopy or certain symptoms of allergy, such as total serum IgE and blood eosinophilia were missing [9]. The main consequence for hospitalized patients who declare having drug allergy is change of the antimicrobial medication with a different class and refrain from any anti-inflammatory and painkiller medication. The situation might be more complicated and has to be more seriously considered for patients who declare multiple drug allergies to various and unrelated molecules.

The term „allergy" is frequently used and one study showed that more than 50% of reported allergies to antimicrobials have no immunologic pattern [10]. Generally, patients tend to overestimate adverse drug reactions and to interpret erroneously new symptoms or signs that occur during treating their disease.

Data from the literature showed that up to 25% of patient's self-report having drug allergies, most commonly induced by antimicrobials, mainly penicillins, followed by sulfonamides, macrolides and cephalosporines [11]. Beta-lactam allergy, recorded in up to 15 % hospitalized population and leading to increased use of broad-spectrum antibiotic use, is confirmed in only 5 % of patients [12].

Having a label of drug allergy or intolerance in the medical record may lead to withholding of first line therapy or even avoidance. It was proved that about 30% of patients having the label of drug allergy to at least one antimicrobial drug received another drug that did not reflect the standard of care [13]. Alternative antibiotic therapy may be less effective or may have less favorable safety profile, leading to treatment failure and increased risk of antibiotic resistance. Trends in antibiotic prescription rates show an increase use of broad-spectrum antibiotics, such as azithromycin and quinolones [14]. It was also proved that total hospital costs with medication were increased for patients caring the label of a drug allergy, with 63% higher antibiotic costs for patients with beta-lactam allergy [15]. Despite the potential deleterious consequences of selecting an alternate medication and the lack of validity of most allergy labels, many clinicians do not take time to complete a comprehensive drug allergy history before prescribing an antimicrobial. It was found that only 4% of patients who declared being allergic to antimicrobial medication on hospital admission had documentation detailing the specific reaction [16]. This finding may be due to the erroneous perception that therapeutic decisions based on an allergy label will not influence the patients' clinical outcome. The ability of health professionals to discriminate between allergy and intolerance, to evaluate the severity of an ADR and the degree of contraindication depends on their level of knowledge in the field of allergic diseases and was evaluated in recent studies and publications [17]. A published survey of physicians practice and knowledge in the field of drug allergies at a university medical center showed that those with any internal medicine training performed significantly better [18].

A recent study evaluating drug allergies in primary care practice in Romania concluded that the medical attitude and competence of family doctors in the field of drug allergies, as well as their collaboration with allergists are not standardized and updated according to guidelines and experts' recommendations [19]. Since primary care physicians play a key role in evaluating patients with possible drug allergies, there is a clear need for pre-and postgraduate allergy educational programs and training [20].

LIMITATIONS OF THE STUDY

Despite being the only study on drug allergy labeling performed in Romania, our study has some limitations. The main limitation is the retrospective analysis of medical records, with relative few and variable information about drug allergies, depending on the level of knowledge of doctors in training, students or nurses who filled in the patient's files. We had no way to verify the proportion of patients from our study with true versus false drug allergy label, based on standardized diagnosis criteria. No follow-up of the patients who experienced allergic reactions during hospitalization was performed.

CONCLUSIONS

We concluded that the impact of drug allergy label is underestimated in hospitalized patients and diagnosis is generally based on patient's history.

The allergy label is overused, most of the patients who self-report drug allergies have no confirmation from specialist and no medical documentation. The main consequences are switch of antimicrobial medication to another class, generally quinolones and avoidance of anti-inflammatory or analgesic medication.

We consider that information referring to drug allergy should be taken by medical staff with minimal training in this field and recorded more detailed in patient's files on hospital admission. Improved collaboration between specialists, including allergists and primary care physicians is needed.

Early in-stent restenosis after revascularization in patients with ST-elevation myocardial infarction

Alice E. Munteanu[1], Camelia Nicolae[2], Irina Florescu[3], Cristina Calcan[1], Daniel Niță[1]

Abstract: *Background and aim: Obstructive coronary disease is one of the most important causes of death worldwide. Percutaneous coronary intervention is one of the most important treatments of this pathology. Using of coronary artery stents represented a major advance in interventional cardiology. While bare metal stents (BMS) set the reference point for improved safety over balloon-angioplasty, first-generation drug-eluting stents demonstrated significant improvements in efficacy, but not necessarily safety, and further technologic developments have focused on optimizing both.*

Methods: We studied 228 patients with STEMI in the last 6 months, divided in 2 groups – in the first group are 122 patients (53.5%) who developed in stent restenosis and the second group has 106 patients had no signs of restenosis (46.5%). The mean time of performing the angiographic reevaluation was 111 days for the first group and 154 days for the second group. The clinical signs that indicate the need of coronary reevaluation was stable angina (116, 50.87%), acute coronary syndrome (58, 25.4%) and asymptomatic patients (64, 28.9%). The cardiovascular risk factors correlate with high risk of restenosis was diabetes (24.3% in first group and 12.2% in the second one, p=0.004), active smoking (p=0.010) and metabolic syndrome (p=0.003). The stent's length >28mm, stent's diameter ≤ 2.5 mm and chronic occlusion correlate with high risk of in-stent restenosis in BMS.

Conclusion: Understanding the importance of risk factors control, will reduce the risk of restenosis, of other cardiovascular event, even sudden death.

Keywords: *stent, early restenosis, STEMI, revascularization*

INTRODUCTION

Cardiovascular disease represents the first cause of morbidity and mortality world-wide.

ST-elevated myocardial infarction (STEMI) represents a challenge for any cardiologist interventionist team who has to decide the best treatment option based on short, medium and long-time prognostic and possible complications.

The first successful percutaneous transluminal coronary angioplasty (PTCA) was performed using a balloon catheter.[1] Due to high rate of coronary occlusion during PTCA and of high rate of in-stent restenosis bare metal stent (BMS) was developed. First studies have shown that BMS are very effective in treating or preventing acute blood vessel obstruction, thus avoiding emergency surgical bypass interventions. Two randomized trials – the Benestend and STRESS (Stent Restenosis

[3] Ana Aslan National Institute of Gerontology and Geriatrics, Bucharest

Study) have shown that stenting lesions de novo on native coronary have reduced angiographic restenosis by about 30% compared to conventional balloon angioplasty.[1,2,3]

Implanting stents leads to a luminal diameter larger than balloon angioplasty, both right after the surgery and in the follow up, thus to a lower restenosis rate.

Using BMS was compared with coronary artery bypass grafting (CABG) in the treatment of obstructive multi-coronary disease in ARTS trial (Arterial Revascularization Therapies Study). The 1 year follow up showed that the mortality, myocardial infarct and stroke rate was similar in the two groups. Survival rate without cardiovascular events was higher in CABG group (87.8% vs 73.8%). Also less surgery patients needed a second revascularization procedure (3.5% vs 16.8%).[4]

Stone et al, studying the safety and effectiveness of BMS and DES on 3006 patients with STEMI with immediate PCI noticed that in DES group the restenosis in stent and recurrent ischemia needing revascularization procedure in 1 year follow up was significant lower than in BMS group.[5] Although, mortality and in stent thrombosis rate were similar for the 2 groups.

Drug eluting stents are a newer coronary stent category, superior to BMS due to a significant reduction of in-stent restenosis, a significant decrease of major adverse cardiac events, as well as target lesion revascularization in those patients which benefited from DES at 6 month follow up.[6, 7] Results at 5 years have demonstrated a similar rate of in-stent thrombosis between the two groups, but a significant lower incidence of major adverse cardiac events in the DES group.[6]

The beneficial using DES is not absolute. DES are superior in reduction of in-stent restenosis incidence especially in high risk lesions. For low risk restenosis patients or for those with high risk of acute in-stent thrombosis due to need of early dual antiplatelet therapy abortion the using of BMS has an important indication.[8,9] Although, lot of research show that using BMS is an alternative for uncomplicated patients or for those with long term dual antiplatelet therapy contraindication, in high diameter vessels, in venous graft lesions or in patient with acute coronary syndrome – STEMI.[10-14]

Despite last decades progresses, in stent restenosis stays an unsolved problem. Revascularization needs in 1 year is 6.7% in DES using, and 11% in BMS, frequently due to restenosis.[15]

METHODS

This study is a unicentric, retrospective, non-randomized trial. The patient from this study were patients of "Academician Vasile Candea" Emergency Clinical Center of Cardiovascular Diseases of the Army Bucharest. We included in the study patients diagnosed with STEMI who underwent myocardial revascularization in less than 24 hours from the appearance of chest pain, who followed the medical treatment according to ESC Guideline, and who underwent angiographic reevaluation in the first 6 months after PTCA. The patients were divided in 2 groups: the study group who developed in-stent restenosis in less than 6 months from PTCA, and the control group who has no signs of restenosis. We evaluate local factors (type of stent, the length and the diameter of stent, the affected vessel and the type of restenosis – focal or diffuse restenosis) and general factors (genetic factors, demographic factors, smoke, and comorbidities – arterial hypertension, dyslipidemia, diabetes, metabolic syndrome, history of stoke, peripheral arterial disease).

RESULTS

We studied 228 patients with STEMI in the last 6 months, divided in 2 groups – in the first group are 122 patients (53.5%) who developed in stent restenosis, from minimal restenosis (24 patients, 20%) to occlusion (16 patients, 13.3%), and the second group has 106 patients which had no signs of restenosis (46.5%). The mean time of performing the angiographic reevaluation was 111 days for the first group and 154 days for the second group.

Most patients came from urban areas (67% for both groups – without significant differences between groups). In the study group the most patients are men (82 patients, 68.3%), while in the other group only 54%

were men (OR=2.476; CI 95% 1.465-3.780; p<0.003). The clinical signs that indicate the need of coronary reevaluation was stable angina (116, 50.87%), acute coronary syndrome (58, 25.4%) and asymptomatic patients (64, 28.9%).

The cardiovascular risk factors correlated with high risk of restenosis were diabetes (24.3% in first group and 12.2% in the second one, p=0.004), active smoking (p=0.010) and metabolic syndrome (p=0.003). The influence of arterial hypertension and dyslipidemia over the risk of in-stent restenosis is hard to appreciate. Prior PTCA, peripheral arterial disease, genetic impregnation also have little correlation with restenosis risk.

The most frequent location of stent implantation in left anterior descending artery (LAD), followed by right coronary artery and circumflex artery, but the stent location doesn't correlate this risk of restenosis.

If we talk about stent's characteristics which can interfere with evolution and prognosis of the patients, the stent's length >28mm (OR 2.77; CI 95% 1.45-4.44; p<0.001), stent's diameter ≤ 2.5 mm (OR 2.45; CI 95% 1.54-3.46; p<0.001), and chronic occlusion (OR 3.78; CI 95% 2.03-7.35; p<0.001) correlate with high risk of in-stent restenosis in BMS. Although, the stent's diameter ≥3.25 mm (OR 0.34; CI 95% 0.24-0.49; p <0.001), the length ≤15 mm (OR 0.58; CI 95% 0.42-0.81; p=0.001) correlate with further restenosis.

DISCUSSION

Our results shows that diabetes mellitus, metabolic syndrome, prior interventional myocardial revascularization, longer stent length and smaller stent diameter are important factors that correlate with risk of in-stent restenosis. Prior PTCA, peripheral arterial disease and genetic factors correlate with restenosis risk. Our research was design to study the risk factors for early in-stent restenosis. Thus, we compared our result with many available researches that studied risk of long term and very long term in-stent restenosis, and results are similar. [16-19] It is known that diabetes, history of myocardial infarction and/or PTCA, different stent and lesion factors correlate with risk of long term and very long term in-stent restenosis, even on BMS or DES.[20-22] Despite rigorous risk factors control and correct medical treatment some patients develop in-stent restenosis, many factors could be incriminated in this phenomenon according with clinical trials. The factors incriminated in in-stent restenosis development, in both BMS and DES, are biological factors (drug resistance, hypersensitivity), mechanical factors and technical factors.[23]

The drugs in DES have a cytostatic (Sirolimus and its analogs) or a cytotoxic effect (Paclitaxel). Statistic data indicate that patients genetic mutations can develop resistance to Sirolimus or Paclitaxel.[24, 25]

Other biological factor is hypersensitivity of compound element in stents. For BMS, release of nickel and molybdenum, and for DES, cobalt releasing, are potential triggers for in-stent restenosis due to local allergic reaction, which can accelerate the atherogenic process.[26, 27]

The mechanical factor responsible of in-stent restenosis are stent underexpansion during the procedure, which is undetectable angiographically, nonuniform drug distribution due to local blood flow alterations, damage of the polymer, stent fracture resulting an important decrease in local drug delivery.[28-31]

Technical factors potentially responsible for increased risk of restenosis include barotrauma outside the stent, randomized clinical trials indicate that restenosis occurred at the proximal margin of stent and uncovered residual plaque, which correlate with increased risk of myocardial infarction at 1 year.[32-33]

Clinical presentation of patient with in-stent restenosis was represented by stable angina in more than half of patients and a quarter of patients were completely asymptomatic. Also, almost ¼ of patients presented acute coronary syndrome, in which smoking and prior myocardial infarction are clinical predictor factors.

Thus, is very important for our patients to understand the importance of risk factors control, reducing the risk of restenosis, of other cardiovascular event and sudden death. Also, there are some biological factors which are difficult to evaluate and some mechanical and technical issues that should be consider in patients with in stent restenosis. Further, we could study the impact of subclinical factors which could interfere with evolution and prognostic, early identifying technics and ways for prevention complications for increase the quality of live and decrease the costs of long term managing of patients.

Economic analysis of hospital/healthcare costs in patients with colorectal digestive anastomosis

Rares Munteanu[1], Traean Burcos[2], Florin Grama[2], Dan Dumitrescu[3]

Abstract: *Intestinal anastomoses have always been a major problem in digestive surgery. With the use of mechanical suture devices, intestinal anastomosis techniques have improved, allowing standardization of methods and shorter duration of surgical procedures. In addition to shortening the operative time, reduced operating room utilization and length of stay (LOS), health financial strain is also reduced by a lower rate of postoperative complications, quicker recovery and socioprofessional reintegration of patients, and by lowering costs related to treating permanent disabilities such as permanent intestinal stoma. The aim of this study was to estimate the costs of surgical patients with colorectal anastomosis (mechanical or manual suturing) and to identify economically efficient surgical techniques. Material and method: Unicentric 10-year retrospective study in the Bucharest "Prof. Dr. D. Gerota" Emergency Hospital. The costs associated with manually constructed and stapled anastomoses in colorectal surgery were compared. Results: In the group with manual colorectal anastomoses (363 patients) the costs per patient were on average 5190 RON and the average hospital stay 14.95 days. In the group with mechanical colorectal anastomoses (97 patients) the average cost per patient was 5037 RON with an average hospital stay of 11.5 days. Conclusions: The use of mechanical colorectal suture devices resulted in a cost reduction of approximately 150 RON per case and a shortening of average hospital stay by 3.45 days. In addition to these direct benefits, we also list the increase in surgical volume (including the diversification of the range of operations) or indirect effects such as faster socioprofessional reintegration of patients.*

Keywords: *intestinal anastomosis, mechanical sutures, costs*

INTRODUCTION

The first gastrointestinal anastomosis was performed over 200 years ago. Since then, the continuous development of medical technologies was accompanied by a continuous improvement of anastomotic techniques with the goal of reducing the complication rate, standardizing the methods, and shortening the operative time. These goals have led to the emergence of mechanical suture devices and the improvement of surgical techniques. Until the use of circular staplers, most patients with rectal tumors underwent rectal resections with removal of the sphincter (rectal amputation). Mechanical sutures made possible low colorectal anastomoses to be performed, significantly

improving patients' quality of life [1]. The use of mechanical sutures has become routine and has a major impact on intestinal sutures. In terms of efficacy, applicability and safety, numerous studies have shown that the use of mechanical suture tools is comparable to manual sutures [2]. Mechanical sutures tends to become indispensable in gastrointestinal tract reconstruction - mainly at the extremities of the gastrointestinal tract (esophagus and rectum) [3,4]. For elective gastrointestinal tract surgery studies that compared mechanical with manual anastomoses found no significant differences between the two methods [5-9].

MATERIAL AND METHOD

We conducted a unicentric retrospective study at the Bucharest "Prof. Dr. D. Gerota" Emergency Hospital between January 1, 2010 and December 31. 2019. All patients admitted to the General Surgery Department who were operated for a colorectal disease were included in the study. Inclusion criteria: age over 18 years, surgery performed during the hospitalization for a benign or malignant colorectal disease which involved performing an intestinal anastomosis to the colon or rectum. Exclusion criteria: intestinal anastomoses performed to resolve a surgical complication from a previous hospitalization. Medical expenses were obtained from medical records, patient discharge form, patient expense account from the HYPOCRATE software, and data from the hospital Accounting Department. The following expenses have been taken into account: accommodation, drugs and medical supply costs, medical tests, investigations from the patient's account, and the average cost of the mechanical suture devices used. The costs related to the training of medical staff regarding the use of the medical equipment used in colorectal surgery (courses, training, etc.) were not taken into account.

RESULTS

At the Surgery Department of the „Prof. Dr. D. Gerota" Emergency Hospital we started using mechanical sutures in colorectal surgery since the 2000s. As with any procedure, there is a learning curve - which is why since 2007 the technique has been used more frequently. Several types of staplers have been used over time - the most frequently used devices and agreed by the operating teams being the GIA two row circular stapler of 60 mm/80 mm/100 mm length, EEA two row circular suture devices 29 mm/32 mm, and Ta Linear Stapler 60 mm/90 mm. There was no experience in the ward (during the study period) regarding the "three-layer" suture or the use of mechanical sutures in laparoscopic interventions. Data on the patients with colorectal diseases who underwent surgery were collected from the Hippocrates database. The collected data were divided into two groups – manual anastomosis and mechanical anastomosis cases (each for malignant and benign diseases), and the following were compared: average LOS, the average cost for each disease, postoperative complications and their costs. Mechanical suture devices were used in the following interventions: colo-colonic anastomosis, ileotransverse anastomosis, colorectal anastomoses, ileal or colonic reservoirs, and appendectomy. Four hundred fifteen patients who underwent surgery for colorectal cancer and respectively 47 patients operated for benign colorectal disease were identified. Among patients with malignant conditions, a predominance of left colon and rectal cancers was observed (approximately 38% and 27%, respectively), and among benign diseases, a relatively similar frequency was found for colorectal inflammatory disease and ischemic intestinal disease (about 36% and 32%, respectively). Average LOS was 14.3 days for cancer and t 15.68 days for benign diseases. The longer hospital stay in patients with benign diseases is accounted for by more days of investigations required before surgery.

Table 1: Malignant cases distribution

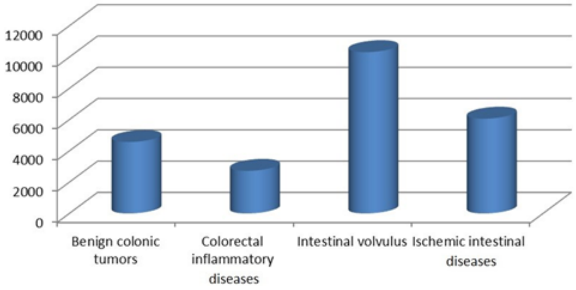
Malignant diseases	Number of cases	Average LOS	Average cost/ diagnosis
Malignant tumors of cecum and right colon	46	15.32	5267.95
Malignant neoplasm of hepatic flexure of colon	15	13.23	5372.79
Malignant tumors of the transverse colon	14	15.22	7134.25
Malignant tumors of splenic flexure of colon	21	16.93	6544.93
Malignant tumors of the left and sigmoid colon	158	12.15	4033.84
Malignant rectosigmoid tumor	46	13.13	4284.48
Malignant rectal tumor	115	14.16	4092.12
	415	**14.30**	**4464.63**

In the case of malignant diseases, the cost of surgical therapy ranged between 4033.84 RON and 7134.25 RON, with an average cost per case of about 4464.63 RON. In the case of benign pathology, the cost per procedure ranged between 2723.75 RON and 10314.33 RON, with an average cost of about 5916.91 RON – which supports the above-mentioned hypothesis that these categories of patients required more investigations before surgery.

Table 2: Benign cases distribution

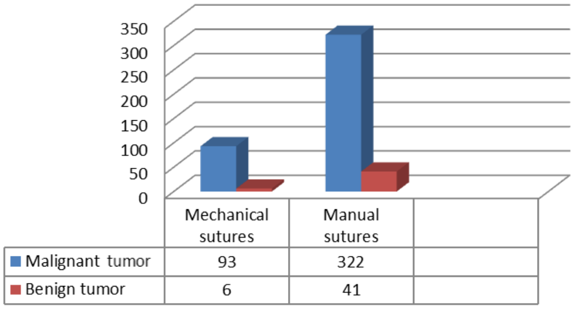
Benign diseases	Number of cases	Average LOS	Average cost/ diagnosis
Benign colon tumors	6	14.33	4569.68
Colorectal inflammatory disease	17	12	2723.75
Intestinal volvulus	9	22.89	10314.33
Ischemic bowel disease	15	13.53	6059.91
	47	**15.6875**	**5916.9175**

Figure 1: Average cost of benign diseases



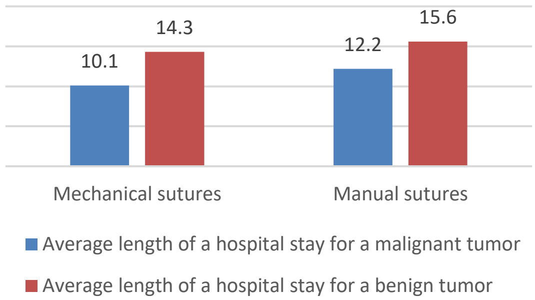
It should be noted that LOS in case of volvulus reaches about 22.9 days, which is associated with an increased cost per hospital stay. This results from an increased share in the medical care costs of accomodation expenses.

Figure 2: Number of cases



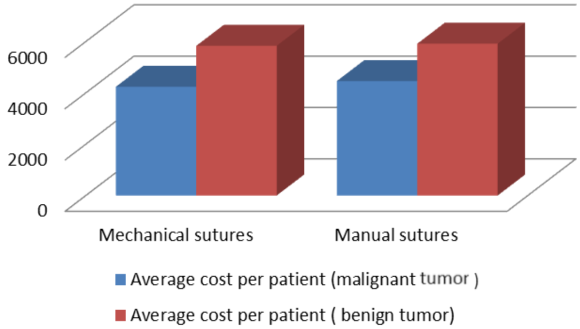
The 2 groups were divided as follows: 363 patients were treated with manual colorectal anastomoses of which 322 were operated for malignant tumors and 41 for benign tumors and a second group of 99 patients who underwent mechanical colorectal anastomoses of which 93 for malignant tumors and 6 for benign tumors (chart 2). As to the average LOS the following differences were found: in the group with mechanical sutures LOS was between 10.1-12.2 days, and in the group with manual sutures it ranged between 14.3 days for malignant tumors and 15.6 days for benign tumors.

Figure 3: Average lenght of stay



In the group with mechanical suture, the costs ranged between 4240 RON for malignant colorectal diseases and 5834.87 RON for benign colorectal diseases. In the group with manual suturing, the costs per case ranged between 4463 RON for malignant tumors and 5916.91 for benign colorectal diseases.

Figure 4: Average costs per pacient



Of the total 462 patients operated for malignant and benign colorectal cinditions, 56 developed surgical complications that required surgical treatment in about half of the cases. The most common complications were intestinal fistulas (about 6%) - a common complication of both mechanical and manual anastomoses. There was no significant difference between the incidences of fistulas in mechanically sutured anastomoses compared to manual sutures.

Table 3: Case distribution according to age and sex

Postoperative complication	Number of cases	Average LOS (days)	Average cost/ diagnosis
Rectal stenosis	2	11,5	3089,1
Intestinal fistula	27	22,9	5532,49
Acute peritonitis	26	19	8930,32
Stoma stenosis	1	15	4447,09
	56	**17,1**	**5499,75**

In the case of anastomotic fistulas, LOS was longer, but the total cost was lower compared to the one identified in the case of septic complications which required broad-spectrum antibiotic therapy that increased expenses. There have also been several technical incidents associated with the use of mechanical suture devices (without them having been ratified or reported) – such as misfiriring or complete device failure during the procedure. Mac Rae et al. reported these incidents as common and associated them with significant morbidity [8]. In our study, no associations were found between intraoperative technical incidents and post-operative complications.

DISCUSSION

The mechanical suturing technique associates a series of benefits such as:

- faster healing of the anastomosis due to better vascularization, less inflammatory reactions of the anastomosis partners, less tissue manipulation, and better tissue alignment [10];
- reduction of septic intervals;
- reduction of operative time;
- technical advantages: can be used in low rectal anastomoses thus allowing the preservation of anal sphincter and significantly improving the patient quality of life
- shorter learning curve than in the case of manual sutures [11, 12];

Despite the above-mentioned advantages, the technique is not perfect and associates anatomical complications such as dehiscence, anastomotic fistulas, and anastomotic stenosis [13, 14]. The advantages and disadvantages of the 2 techniques should be discussed with the patient before signed informed consent is obtained [15]. On the other hand, it is important for health-care providers to report adverse events to manufacturers, to provide feedback helping the manufacturere to improve the design of these devices [13, 16]. The most commonly encountered complication remains the anastomotic fistulas. Reintervention and complications such as anastomotic fistulas are considered quality indicators in colorectal surgery. Anastomotic fistulas are among the most feared complications, especially after colorectal resections and are associated with increased morbidity and mortality, with a high reintervention rate, and increased LOS [17-21]. The prevalence of anastomotic fistulas after colon or rectal resections varies depending on anatomical location, with a lower frequency in the case of right-sided colon anastomoses. The incidence of radiologically identified anastomotic fistulas ranges between 0.5% and 21%, but of these only 1-12% are clinically significant anastomotic leaks after colorectal surgeries and up to 10-14% in low colorectal resections [10]. Overall, patients with anastomotic fistulas developed after colorectal surgery have a significantly higher risk of morbidity (56%) and mortality (32%) [10]. It is also associated with a significant economic burden because of multiple reinterventions, radiological procedures, the stomas needed to control fistulas and because of the increasing length of hospital stay [22]. Anastomotic fistulas are documented as a strong indicator that is associated with high costs in colorectal surgery and also with significant long-term costs for the patient and the health system due to the high rehospitalization rate (risk that is 1.3 times higher in the first 30 postoperative days in patients who have anastomotic fistula compared to those who do not have fistula after colorectal surgery). Also, high reintervention rates, increased incidence of postoperative infections, and longer LOS per admission increase the cost (in the literature was estimated on average at about 7 additional days) [23-26]. Factors of increased peritoneal aggression are known to cause adhesions, one of he most frequent causes of long term morbidity after abdominal surgeries [27-29]. The use of mechanical suture devices shortens the average surgical procedure by 15 minutes on average – from which benefits the patient by reducing anesthesia surgical stress and administrative costs, especially in hospitals with high workload. These have direct implications on the cost associated with anesthesia procedures and on increasing the utilization rate of the operating room, thus allowing more surgeries to be completed. The evaluation of the benefits related to shorter LOS and less medical care days due to a reduction in morbidity, in terms of the costs of using mechanical sutures, must be addressed to each situation, these being more obvious in clinics performing numerous esophageal and colorectal surgeries [12]. Reducing the costs for surgical patients and in particular for a patient with gastrointestinal surgery is a goal in the management of surgical patients.

CONCLUSIONS

Mechanical suturing technique must be mastered by each surgeon and the necessary devices must be found in each surgery department. Although the cost of these devices is high, overall, it seems that the cost/effectiveness ratio is in their favor. In addition to shortening the duration of colorectal surgeries, increasing the use of operating rooms, decreasing the LOS, the financial effort is reduced by a lower rate of postoperative complications, faster socioprofessional reintegration of patients, and lower costs related to treating permanent disabilities such as permanent intestinal stoma, directly influencing the decrease in costs associated with surgical patient care. An important component of surgical patient management is cost reduction, which can be achieved by reducing LOS and careful management of the case by selecting an appropriate surgical technique.

REVIEW

Effect of Hydroxychloroquine, Favipiravir, Lopinavir/Ritonavir, Remdesivir, Umifenovir, and Interferon beta-1a in Covid-19 patients: A systematic review of Randomized Clinical Trials

Mehran Pezeshki[1], Hadi E. Gouvarchinghaleh[1], Amirhossein Ghahremanian[2], Mihnea A. Găman[3], Mahdieh Farzanehpour[1]

Abstract: *Background: Coronavirus disease 2019 (COVID-19) was recognized by the World Health Organization (WHO) as a global pandemic on March 11, 2020. Since then, researchers worldwide have focused their attention on identifying effective treatments and developing vaccines to combat this disease.*

Aim: To report the effectiveness of the drugs employed in the COVID-19 treatment protocols based on data from clinical trial studies conducted from the beginning of the pandemic until December 10, 2020.

Methods: Following the PRISMA guidelines, we conducted an advanced search in several electronic databases. A total of 13553 studies was screened by two people simultaneously and separately based on the article title, abstract and full-text. The quality of the studies was evaluated using the Cochrane criteria.

Results: Of the 13553 studies identified, 50 clinical trials were included in this systematic review. Of these, three studies explored the use of remdesivir, nine studies the use of hydroxychloroquine, five studies the use of lopinavir/ritonavir, six studies the use of favipiravir, one study the use of tocilizumab, two studies the use of interferon beta-1a and two studies the use of umifenovir.

Keywords: *Hydroxychloroquine, Favipiravir, Lopinavir/Ritonavir, Remdesivir, Umifenovir, Interferon beta-1a, Covid-19*

INTRODUCTION

Since December 2019, a new coronavirus, known as the novel coronavirus 2019 (nCoV-2019), has become the cause of a pandemic and a serious threat to global health. This coronavirus was first observed in Wuhan and has managed to spread all around China and ultimately worldwide [1]. The severe acute respiratory syndrome (SARS) Corona Virus 2 (SARS-Cov-2) is now recognized as the cause of coronavirus disease 2019 (COVID-19) and as a new member of the family of coronaviruses [2], being introduced by the World Health Organization (WHO) as the cause of the ongoing pandemic. The COVID-19 pandemic has spread rapidly around the world. By the end of 2020, nearly 100 million people have been diagnosed with this respiratory illness, of which about two million have already died [3]. COVID-19 can be present with no symptoms. The affected subjects may experience mild to severe symptoms of fever, chills, muscular pain, fatigue, cough, rhinorrhea, nasal congestion, and dyspnea, which can ultimately lead to life-threatening pneumonia. In addition, gastrointestinal symptoms, conjunctivitis, anosmia and ageusia have been associated with the diagnosis of COVID-19 [4]. This illness spreads by respiratory droplets and aerosols during coughing and (or) sneezing. The primary prevention protocol includes the use of face masks, environmental hygiene, and suitable hand washing. The majority of patients who died from COVID-19 had comorbid conditions, e.g., hypertension, diabetes, cardiovascular diseases, chronic obstructive pulmonary disease, malignancies, and chronic liver disorders [5]. tomography (CT) of the chest, the most common patient findings include bilateral pulmonary changes, yet unilateral involvement has also been reported. Also, alterations of laboratory biomarkers like: leukocytosis, leucopenia or lymphopenia, an increase in the prothrombin time (PT), a decrease of the hemoglobin and an increase in the erythrocyte sedimentation rate (ESR) have also been reported. Moreover, an increase in the respiratory rate (>30 per minute), an oxygen saturation fall (≤93%), a decrease in PaO2/FiO2 (<300), and an increase in pulmonary infiltration (>50% of the lungs during 24 to 48 hours) accompany the clinical presentation of COVID-19 [4]. The mortality rate of COVID-19 is lower than the previous epidemics, namely 10% for SARS and 34% for Middle East Respiratory Syndrome (MERS). However, COVID-19 is more contagious and has a more extended incubation period, with SARS-CoV-2 infecting a larger population and causing public panic and an impressive economic impact [6]. Moreover, since there was no effective COVID-19 treatment and vaccines were not yet available, the pandemic has forced healthcare providers and regulatory organizations into repurposing current medicines aiming to test their potential efficacy in the management of COVID-19. For this reason, several clinical trials have been undertaken or are currently conducted worldwide. In some countries, physicians have prescribed medicines employed in the management of non-infectious diseases, such as chloroquine and hydroxychloroquine (used for malaria and rheumatoid arthritis), or antiviral Food and Drug Administration (FDA) approved drugs such lopinavir/ ritonavir, favipiravir, remdesivir, etc., incorporating the use of these pharmacological agents in the local COVID-19 therapy guidelines [7]. Thus, the purpose of this systematic review and meta-analysis was to assess the efficacy of these drugs in the treatment of COVID-19 patients.

MATERIALS AND METHODS

All procedures outlined in this review were performed based on the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement [8]. The literature was searched with related keywords to ensure that no similar studies have been conducted recently. Subsequently, a structured study question was extracted and used to define keywords, possible combinations, and a search strategy. Then, the literature was systematically searched again in relevant databases. We systematically searched PubMed/MEDLINE, Cochrane Library, Scopus, and Embase from inception until December 10, 2020. The following keywords were used:

Drugs:

- Hydroxychloroquine, Plaquenil®, Hydroxychloroquine Sulfate
- Chloroquine, Chloroquine Sulfate, Resochin®, Dawaquin®, Lariago®
- Remdesivir, Veklury®, Covifor®, Remivir®, GS-5734®, Bemsivir®, BDREM-100®
- Favipiravir, Avigan®, Fabiflu®, Favicovid®, Avifavir®, Areplivir®, Favipira®
- Lopinavir/Ritonavir, Kaletra, Lopimune®, Aluvia®, LPV/r,
- Umifenovir, Arbidol, AR-1I9514, Arpeflu®
- Tocilizumab, Actemra®, Roactemra®
- Interferon beta-1a, Rebif®, ReciGen®
- Disease: COVID-19, SARS-CoV-2, Coronavirus disease 2019.

For each database, an appropriate search was computed, e.g., using MeSH keywords. To increase the sensitivity, we checked the reference lists of the identified clinical trials and of the review articles. Moreover, a manual search of relevant websites was carried out. All the identified articles were imported into the EndNote software (Version X8, Thomson Reuters, New York). After eliminating duplicates, we screened the articles based on their title, abstract, and full-text according to our inclusion and exclusion criteria. We included studies based on the following criteria: 1) Study population: adults receiving the drugs as mentioned above for COVID-19 treatment but not for COVID-19 prevention. 2) Intervention: the use of the aforementioned drugs 3) Comparator: standard of care, placebo, any other drug or combination 4) Outcome: efficacy, treatment rate, reduced length of hospitalization, viral load, and mortality reduction 5) Study design: published clinical trials, but not preprinted articles. Two reviewers screened the titles, abstracts, and full-texts separately based on the eligibility criteria. Any disagreements in scoring were resolved through discussions with the senior author. Two distinct reviewers assessed the quality of the randomized clinical trials (RCTs) using the Cochrane Collaboration tool [9]. The procedure used to evaluate the quality of clinical trials evaluated the following criteria: random sequence generation (selection bias), allocation concealment (selection bias), blinding of participants and personnel (performance bias), blinding of the outcome assessment (detection bias), incomplete outcome data (attrition bias), selective reporting (reporting bias), and other biases. We rated each trial as having a low, unclear, or high risk of bias. After inspecting the quality of the clinical trials, we designed an extraction data form based on previous review articles, in addition to employing the Cochrane extraction form for data gathering. Two separate authors extracted the data from the included articles. The extracted data included study specifications (design, duration of intervention, duration of follow-up), participants' specifications (number, age, and gender), intervention specifications, and measured outcomes.

RESULTS

Twenty-eight clinical trials were selected from the 13553 screened studies.

Table1: Included studies

Author	Country	No of pts	Severity	Intervention	Control

HCQ: hydroxychoroquine, AZM: Azithromycin, FVP: Favipiravir, LPV/R: Lopinavir/Ritonavir, UMF: Umifenovir, RMD:Remdesivir, TCZ: Tocilizumab, IFN b-1a: Interferon beta-1a, SC: Standard Care, Pl: Placebo and NR: Not reported.

Chloroquine and Hydroxychloroquine with or without Azithromycin:

Both medications were formerly administered to treat malaria and rheumatoid arthritis. According to their mechanism of action, they could be potentially effective in the treatment of COVID-19. Hydroxychloroquine does not bind to the angiotensin-converting enzyme 2 (ACE-2) receptor directly but increases the acidity of the medium in which the COVID-19 protein-spikes interact with and attach to the ACE-2 receptors. The resulting acidity degrades the viral spike and reduces the infection rate, eventually impeding the spread of COVID-19 [1]. Moreover, azithromycin seems to constrain SARS-CoV-2 via direct binding to the ACE-2 receptors. Cavalcanti et al. analyzed hospitalized patients with mild to moderate COVID-19 and revealed that hydroxychloroquine alone or in combination with azithromycin was not associated with better outcomes within 15 days after treatment initiation as compared to standard care. Moreover, there was no significant effect on mortality or mechanical ventilation [3]. Similarly, Horby et al. showed that the treatment with hydroxychloroquine was not associated with a lower mortality rate in hospitalized patients with COVID-19 within 28 days versus conventional therapy [4]. Besides, after 3-7 days of treatment with hydroxychloroquine, the RNA viral load in the nasopharyngeal swab samples did not decrease. Also, this regimen did not reduce the duration of the complete resolution of the symptoms in patients with mild to moderate COVID-19 [5].

In other studies, hydroxychloroquine did not exert antiviral effects against SARS-CoV-2 and was not associated with symptom relief in outpatients with early, mild COVID-19 [7, 10-12]. In addition to their ineffectiveness in COVID-19 patients, treatment with hydroxychloroquine and chloroquine was associated with severe adverse drug reactions (ADR), i.e., depression, psychosis, insomnia, and increased risk of suicide [13]. These two drugs tend to cause QT-prolongation, which is a serious ADR. Thus, necessary cautions must be taken into account when are administered in combination with other medicines with similar side effects, such as azithromycin [3,14-16]. On the contrary, Chen et al. examined 48 patients with COVID-19 and indicated that hydroxychloroquine could reduce the duration of hospitalization [17]. Guerin et al. and Lagier et al. revealed that hydroxychloroquine combined with azithromycin contributed to symptom relief in COVID-19 patients [18,19]. Moreover, Arshad et al. demonstrated that hydroxychloroquine+ azithromycin reduced the mortality rate versus both medicines alone [19]. Overall, according to our review, hydroxychloroquine and chloroquine could not prevent or treat mild to moderate or severe COVID-19.

Favipiravir:

Favipiravir inhibits the RNA-dependent RNA polymerase enzyme, resulting in the inhibition of viral RNA synthesis [20]. Doi et al. showed that the viral load was not significantly different in patients who received early versus late treatment with favipiravir. Additionally, Chen et al. stated that favipiravir was not as effective as umifenovir in improving clinical symptoms [21]. Likewise, in a study by Lou et al., the therapy based on favipiravir was comparable to standard care [22]. However, in other studies, favipiravir was associated with a reduced time of recovery compared to the control group [23, 24]. Furthermore, Zhao et al. showed that the combination therapy of tocilizumab and favipiravir reduces pulmonary inflammation [25]. Hyperuricemia, hypertriglyceridemia, nausea, vomiting, and diarrhea are the reported ADRs for this medicine [21, 23, 26].

Lopinavir/Ritonavir:

Lopinavir/ritonavir inhibits the 3CL pro in vitro, a protease present in the severe acute respiratory syndrome-associated coronavirus (SARS-CoV) and highly conserved in SARS-CoV-2 [27]. Ye et al. showed that a combination of Lopinavir and Ritonavir was more effective in the resolution of fever and other clinical symptoms and signs in comparison to conventional therapy [28]. In contrast, Li et al. showed that lopinavir/ritonavir does not seem to improve the clinical outcome of adult patients with mild to moderate COVID-19 and has little benefit over supportive care [29]. Similarly, in Cao's study, there was no significant difference between the standard care and this regimen in hospitalized patients with severe COVID-19 [30]. Also, the UK Recovery Study compared 1596 patients receiving lopinavir/ritonavir with 3376 patients receiving standard care, and no benefit was observed [31]. In another study by Hung and Deng, the combination therapy of methylprednisolone or umifenovir with lopinavir/ritonavir seemed to improve clinical outcomes, e.g., shortening the duration of viral shedding and hospital stay [32,33]. All in all, at the moment, lopinavir/ritonavir cannot be recommended as mainstay therapy for COVID-19 since there is little supportive evidence regarding its efficacy against COVID-19.

Remdesivir:

Remdesivir is a monophosphoramidate adenosine analog that targets and inhibits the RNA-dependent RNA polymerase enzyme [34]. Grein et al. revealed that 68% of their patients with severe COVID-19 responded to treatment with remdesivir, which improved their health status [35]. Similarly, in a study by NIH, the treatment with remdesivir was associated with a reduction of the recovery time and a lower mortality rate [36]. Thus, remdesivir was authorized for emergency use by the FDA, the European Medicines Agency, and the National Health Services in the UK [37-39]. Moreover, in Goldman's trial, there was no significant difference between a 5-day course and a 10-day course of remdesivir in adults with severe COVID-19 not requiring mechanical ventilation [40]. Although hospitalized adults with severe COVID-19, remdesivir did not yield significant clinical benefits, early treatment in the course of the disease was associated with less recovery time [41]. Accordingly, remdesivir is a promising treatment option in COVID-19 and was the first drug to acquire FDA approval to treat COVID-19 [42].

Umifenovir:

Umifenovir protects the body against viral infections via blocking the viral entrance to host cells. Yethindra et al. revealed that patients with mild to moderate COVID-19 might benefit from umifenovir combined with standard care. Also, minimal adverse side effects were reported [43]. In addition, umifenovir monotherapy seemed to be superior to lopinavir/ritonavir in treating COVID-19 in a small sample size study [44]. Umifenovir, and supportive care, may relieve fever and other symptoms faster in COVID-19 patients, but it needs further investigation [45].

Tocilizumab:

A 3rd generation monoclonal antibody (humanized mAb), tocilizumab, inhibits interleukin-6 (IL-6) receptors and is used in the treatment of rheumatoid arthritis and other autoimmune diseases. Patients with severe cytokine release syndrome (CRS), and probably severe pneumonia, may also benefit from tocilizumab [46]. Toniati et al. recorded a rapid and sustained response to tocilizumab and observed a post-therapy clinical improvement [47]. However, Kewan et al. did not report significant clinical improvement with tocilizumab in patients with severe COVID-19 [48]. In addition, tocilizumab tends to decrease the mortality rate and the need for invasive mechanical ventilation in adults with severe COVID-19 pneumonia [49]. On the contrary, Colaneri et al. (2020) studied 112 adults with severe COVID-19 and showed that mortality or the number of intensive care unit (ICU) admissions was not reduced following the administration of tocilizumab [50]. Likewise, Kewan et al. did not observe a significant clinical improvement with tocilizumab in patients with severe COVID-19 [51]. Therefore, due to contradictory results, further studies are needed to establish the beneficial effects of tocilizumab in patients with severe Covid-19.

Interferon beta-1a:

Davoudi et al. reported that treatment with interferon beta-1a did not change disease duration. However, when this medication was added to the nationwide approved therapy regimens, an increased discharge rate on day 14 and a decreased 28-day mortality were detected [52]. Moreover, another study supports the use of interferon β-1a in combination with hydroxychloroquine and lopinavir/ ritonavir in the treatment of COVID-19 [53].

DISCUSSION

This systematic review provides a comprehensive analysis of clinical trials exploring the use of hydroxychloroquine, chloroquine, favipiravir, lopinavir/ritonavir, remdesivir, tocilizumab, and interferon beta-1a in COVID-19 patients. Despite the previous suggested benefits of chloroquine or hydroxychloroquine with or without azithromycin, these agents could not show favorable efficacy in the prevention or treatment of COVID-19. The occurrence of severe ADRs, i.e., QT-prolongation, which can enhance the interactions with other medicines and pose serious health threats, have obliged the National Institute of Health and the WHO to abolish these medicines from their trials. Lopinavir/ritonavir, formerly used to treat human immunodeficiency virus (HIV) infection, had no effect on the inhibition of virus replication, reduction of the duration of hospitalization or mortality, leading to the withdrawal of this drug from clinical trials. Favipiravir, a guanine analog, and umifenovir have been approved in some countries, e.g., Russia, but further research is warranted to clarify their effects in COVID-19. Some countries, despite their former approval of these medicines, later withdrew them from their national COVID-19 guidelines. Remdesivir is the first FDA-approved pharmacological agent for COVID-19, and its efficacy was observed in some multicenter, randomized, controlled trials. However, since these RCTs were funded by pharmaceutical companies, there is a risk of bias regarding their benefits. Moreover, there are some meta-analyses that described non-significant effectiveness on COVID-19 outcomes in comparison to standard care. Overall, more studies with a lower risk of bias are needed to enable confident statistical analyses. The IL-6 receptor blocker, tocilizumab, might be a robust anti-inflammatory agent in the management of severe COVID-19 patients during the inflammatory pneumonia phase. There are some other ongoing trials on tocilizumab that will be reported in the following updates. Although interferon beta-1a showed favorable efficacy in a phase 2 trial, more investigations are needed due to the high risk of bias and small sample size of this exploration. Our study analyzed only published RCTs, not observational studies (cohorts, case reports, and case series). According to different interventions, different doses, and different disease severity, more studies are needed to conduct reliable meta-analyses or dose-response studies.

CONCLUSION

The rapid transmission of SARS-CoV-2 has limited the opportunities to develop new treatment strategies. Thus, a try-and-error strategy was used to test medicines in the management of COVID-19 and develop standard treatment guidelines. Our findings suggest that hydroxychloroquine, chloroquine, and lopinavir/ritonavir are not favorable treatments for COVID-19. Favipiravir, umifenovir, and interferon beta-1a need investigation in more clinical trials as well. Tocilizumab and remdesivir might be effective in some COVID-19 patients, but more research is needed to draw conclusions.

ORIGINAL ARTICLE

Effect of different physical stressors on soldier's psychophysiological response and marksmanship

José F. Tornero-Aguilera[1,2], Jaime Gil-Cabrera[1], Vicente J. Clemente-Suárez[1,2,3]

Abstract: *Shooting impairment may occur whereas there is either central or peripherical fatigue. However, the effects of different physical stressor stimuli on fine motor skills as shooting are yet not fully understood. The present research aimed to analyze the effect of endurance and resisted physical stressors on the psychophysiological response and pistol marksmanship of novel soldiers, and the possible differences in gender and BMI. Variables of heart rate, isometric hand strength, rate of perceived exertion, and pistol marksmanship were analyzed in 56 soldiers in endurance and resisted stress protocols. Isometric hand strength, heart rate, and RPE were significantly higher in both resisted and endurance physical stress protocols than in the basal sample. Gender differences were seen in strength, cardiovascular and RPE values. Also, subjects with larger BMI presented significantly higher isometric hand strength and higher marksmanship in all moments evaluated. We conclude that an endurance stress protocol produced a higher cardiovascular and perceived exertion than a resisted one, not affecting hand strength, shooting heart rate, and marksmanship. Females presented lower hand strength and marksmanship while higher rated of perceived exertion and heart rate during the endurance and resisted stress protocols than males. Overweight participants presented higher heart rates during both physical stress protocols, but higher hand strength and marksmanship while similar shooting heart rates than normal-weight participants.*

Keywords: *marksmanship; stress; heart rate; fine motor skills; fatigue*

INTRODUCTION

The effect of different stressor stimuli on fine motor skills is an area with wide applications, yet not highly developed. The stress effects may differ regarding the characteristics of the stressor stimuli. In the case of physical exercise, the intensity, duration, and type of exercise have a direct impact either on fine or gross motor skills [1].

Authors found how after a bout of high-intensity, lower-body resistance training passing accuracy was decreased [2]; after cycling in an ergometer at 100% of maximal capacity, significant attenuation on reaction times was found, like at lower intensities (70%) [3], suggesting an inverted-U function between exercise intensity and motor control.

Specifically, in combat, previous researchers found no effect on marksmanship despite the increased combat stress, neither with rifles and pistols independently of the caffeine ingestion [4,5]. The physiological mechanisms underlying the decrease of performance on fine motor skills may be related to i. the accumulation of hydrogen ions, which affect glycolytic enzymes due to low Ph, impairing ATP production and compromising the contractile capacity of the muscle [6]; ii. the high inorganic phosphate concentration, which inhibits Ca ++ reuptake increasing its concentration in the sarcoplasm and hindering muscle contraction; and iii. the ammonia concentration, which is related to the affection of neurobiological processes, affecting the quality of neural connections and electrical activity of the muscle [7].

In addition, all these acute metabolic responses are directly modulated by the intensity and type of exercise [8]. Related to shooting accuracy and marksmanship, previous authors showed that high-intensity exercise affected central aspects

of shooting performance, shooting accuracy, shooting precision, and stability of hold, being accentuated when shooting in a standing position, compared with shooting in a prone position [9]. Acute protocols designed to fatigue the upper body flexor muscle groups (muscles involved in stabilizing and supporting a firearm), such as lifting, climbing, and pulling, presented significant decreases in rapid-fire rifle shooting performance in the standing position in soldiers immediately after these exercises [10]. In this line, independently of the type of exercise (concentric, eccentric, or a combination of both) or the location (knee, ankle, or entire lower extremity), acute fatigue may induce a loss of stability[11]. This fact, directly affects postural, standing, and gun stability, key factors connected to rifle shooting accuracy 12 since body sway and imbalance has been directly correlated with poor shooting score[13,14]. Superior shooting performance requires good postural balance, as well as, an ability to steady the gun while aiming[12]. However, the effect of different acute stress exercise-induced peripheral fatigue on fine motor skills such as shooting is yet not well documented. Most of the studies have focused either on soldiers or experienced subjects, showing how lower fitness levels, experience, and training increased fatigue and decrease marksmanship [15,16]. In addition, previous studies were the focus on the rifle, showing lower research on pistols, leading to greater muscular fatigue due to the farther center of mass to the shooter's body and the increase in joint angle [17]. Thus, we proposed the present research to analyze the effect of endurance and resisted physical stressors on the psychophysiological response and pistol marksmanship of non-experienced shooters. As a second aim, we aimed to analyze differences in gender and weight. We hypothesized that i. resisted physical stressor would produce a higher psychophysiological stress response, decreasing the marksmanship more than the endurance exercise stressor; ii. Subjects with higher body mass index (BMI) would present higher psychophysiological response and lower marksmanship; iii. There would be gender differences in the psychophysiological stress response and marksmanship.

MATERIALS AND METHODS

Participants

A total of 56 soldiers belonging to light military forces (23.6±3.7 years; 175.8±9.1 cm; 71.3±8.7kg; 23.1±2.2 BMI) were analyzed. Inclusion Criteria were: Professional Experience in the army. Exclusion Criteria for were: Presence of any medical condition or injury that would be a limiting factor for intense physical activity and the use of firearms (e.g. cardiovascular diseases) at the moment or during the protocol, intake of any dietary supplement, stimulants, or other ergogenic aids. Participants were informed of the characteristics of the study and the potential risks derived from those who were exposed. All the procedures were conducted following the Helsinki Declaration (as revised in Brazil, 2013), all the participants filled out an informed consent form previous to starting the research, and all the procedures were approved by the University Ethic Committee.

Methods

Procedures

Before the research started all the subjects received instructions/familiarization regarding the protocol and tests. Then 3 days of evaluation were distributed as follows: 1º Day: basal sample of all the variables measured in the study; 2º Day: 48h after, subjects performed randomly an endurance or resisted physical stress protocol; 3º Day: 48h after, subjects performed the remaining protocol.

For both physical stress protocols, participants conducted a warm-up composed by:

i) 2 min of joint mobility

ii)5 min of light aerobic running (50-60% Maximum Heart Rate)

iii) 2 series of 20 m of progressive running intensity

After the warm-up, participants performed the physical stress protocol, which was supervised and encouraged by sports science professionals:

Resisted Physical Stress Protocol

- 20 sets of burpees at maximum intensity

Endurance Physical Stress Protocol

- 5 min maximal running test in a track field.

Before the research, body weight was assessed with a SECA scale model 714 with a precision of 100 grams (range 0.1-130 Kg), located on a flat and smooth surface and calibrated at zero. Subjects were barefoot and with minimal clothes. Once located in the center of the platform, they remained without their body being in contact with surrounding objects, with the weight evenly distributed on both feet facing forward. Height, with a SECA scale model 714 with a precision of 0.1 mm (range 60-200 cm). The subject stood up, barefoot with the head oriented in the Frankfurt plane. Arms on both sides of the trunk and fully extended with palms touching the external face of the thighs, heels together touching the lower end of the vertical surface with the inner edge of the feet, occipital area, scapular, buttocks, posterior face of the knees and calves touching the vertical surface of the anthropometer.

Before and after the exercise stress protocols, we measured:

- Rating of perceived exertion (RPE), 6–20 scale.

- Isometric hand-grip strength using a TKK 5402 dynamometer (Takei Scientific Instruments CO. LTD). Each participant's grip strength was measured on the shooting hand. Participants were standing with 0 degrees of shoulder flexion, 90 degrees of elbow flexion, and the forearm in neutral. Idem, was done pre-post and among series.

- Heart Rate (HR) was measured before and during the entire protocol by a Polar V800 HR monitor (Kempele, Finland).

- Marksmanship was measured by the sum of three airsoft pistol shots to a target at a distance of 7 m, following procedures of previous research [4,5]. A gas blowback Beretta 92X Centurion airsoft gun (450 fps) was used.

Statistical analyses

To analyze the data, we used the SPSS statistical package (version 24.0; SPSS, Inc., Chicago, Ill.). Means and standard deviation (SD) were calculated using traditional statistical techniques. Normality and homoscedasticity assumptions were checked with a Kolmogorov-Smirnov test. To analyze differences between pre and post a T-test was administered, and to analyze differences between experimental groups (gender and BMI) and differences between moments of evaluation, an ANOVA test was conducted since variables presented a parametric distribution.

RESULTS

The results are reported as mean±SD. Isometric hand strength, HR, and RPE were significantly higher in both Resisted and Endurance physical stress protocols than in basal samples (Table 1).

According to gender differences, males present significantly higher isometric hand strength at all moments evaluated. HR at shooting at Basal and Endurance physical stress protocol of females was statistically higher than males. Female RPE was higher than males at Resisted and Endurance physical stress protocols (Table 2) (between parenthesis significant differences (p≤0.05) between males vs females).

Subjects with larger BMI (BMI ≥25 overweight) presented significantly higher isometric hand strength at Basal and Resisted physical stress protocol than subjects with lower BMI (BMI<25). Subjects with larger BMI also presented higher marksmanship in all moments evaluated (Table 3) (between parenthesis significant differences (p≤0.05) between BMI<25 vs BMI≥25).

Table 1: Psychophysiological parameters analyzed before and after the physical stress protocols

	Basal	Resistance Training	Endurance Training	F	P	η2	Moment comparison

DISCUSSION

The present research aimed to analyze the effect of endurance and resisted physical stressors on the psychophysiological response and pistol marksmanship of non-experienced shooters. Our hypotheses were partially completed since i. There were no significant differences in stress protocols in the psychophysiological stress response or marksmanship. ii. A similar psychophysiological response was found independently of the BMI, but subjects with larger BMI presented higher marksmanship values. iii. There were gender differences in the psychophysiological stress response and marksmanship.

The cardiovascular response monitored at the basal time was higher than the considered standard for the population evaluated (60-70 bpm) [18]. This was consistent with an anticipatory anxiety response, a defense organic response modulated by the activation of the sympathetic nervous system that prepares individuals for any uncontrolled or new stimuli [19]. Previous authors reported a significant increase in the heart rate from a standing resting position to a standing position firing a gun, in line with the results obtained in the present research [20].

The cardiovascular response has a direct impact on fine motor skills as shooting, the higher HR shortens the diastolic phase and increases the systolic one, increasing body tremor [21], which in addition to the one produced by physical activity, marksmanship could be compromised [22,23]. After resisting and endurance physical stress protocols we found a significant increase in the cardiovascular response to shooting (38.6% and 46% respectively), however, marksmanship was not affected, suggesting no negative effect on shooting HR and fine motor skills.

In this line, previous authors obtained similar cardiovascular results, without a marksmanship compromise in archers [22] and pistol shooters [24]. The lack of significant differences in marksmanship between the two stress protocols highlighted the no effects of peripheral fatigue on shooting performance.

There are three possible hypotheses which would explain this: i) Subjects performed both resisted and endurance physical stress protocols with an optimal arousal level [25,26], in accordance with the Inverted-U hypothesis which predicts that performance is best at a moderate optimal level and becomes progressively worse with either increases or decreases in arousal, and comes to confirm that incorporating psychological factors in training (e.g. pressure), may enhance performance [27,28]; ii) Since subjects have none previous experience and despite performing a familiarization, as consequence of low total acquired experience, fatigue did not affect their marksmanship values; iii) Among the familiarization, breathing and holding techniques were taught to the subjects, which are essential to attenuate the postural tremors created by possible high HR at the moment of shooting, technique which has proven essential for rifle, pistol [15] and arch [22], the use of these techniques could be another possible explanation.

The ability to stabilize a gun is crucial for performance in pistol shooting, being related to the shooter's muscular strength [29]. The maintenance of isometric hand strength can play an important role in this fact, highlighting the importance of physical fitness for athletes and professionals that have to use fire weapons (such as biathlon athletes, or police and military respectively).

Previous authors proposed integrated operative high-intensity interval training as one of the best training tools for this aim since it allows participants to improve both, muscular and cardiovascular performance, two factors directly related to shooting performance [30,31]. In this line, both protocols elicited a significant increase in HR during its execution, being higher in the endurance stress protocol.

This cardiovascular response could be related to the continuous impact, load, and physiological demand of this type of work, a fact consequent with previous studies which compared similar exercise-based protocols [31,32]. The HR reached during the two stress protocols is associated with a decrease in fine motor abilities and specifically in shooting, a fact basic for any shoot actions independently performed by arch [33] pistol or rifle [24].

Nevertheless, at the shooting moment the HR decreased below 140 bpm, HR is not related to this fine motor abilities impairment.

These results highlighted the importance of cardiovascular stress response control in these activities, emphasizing the importance of a good aerobic physical condition for these activities. Females presented lower isometric hand strength values at all moments evaluated. This could be explained due to the female phenotype since they present lower body and muscle mass than males, lower baseline testosterone levels, and lower strength in the upper body muscles [34]. Previous authors also found similar results when comparing the hand grip of active handball and judo female athletes with healthy male subjects, presenting males with higher hand grip strength than females [35].

RPE seems to be also influenced by gender. Females presented higher RPE in the endurance and resisted physical stress protocols. These gender differences were also found in weight-bearing as treadmill [36,37,38], partial weight-bearing as ski machine [38], and non-weight-bearing as cycle [39]. Mechanisms underlying this apparent gender difference cannot be specified, however, there are several hypotheses as information processing [40] and physiological [41] differences as plausible explanations. In this line, previous authors suggested that gender differences in RPE may exist in the fact that females rate exercise as more effortful than males at absolute levels of power output [42].

Finally, a higher cardiovascular response during the protocols and while shooting at basal and endurance stress protocol was presented by females. These differences are related firstly to their smaller myocardium, beating slightly faster to make up for its size. While the average basal male heart beat is around 70-72 bpm, women's beats are 78-82 bpm [43]. Secondly, the increased basal heart rate would explain the aforementioned anticipatory anxiety response, which increases the heart rate due to perceived stress and novelty of the stimuli [19]. The response has been also evaluated in sports competition tasks [44] or novel paratroopers before jumping [45] with a similar physiological response. Thirdly, the lower recovery capacity after short burst high-intensity endurance activities of females [46], may explain the significantly higher shooting heart rate than males after the endurance stress protocol. BMI cutline was established at normal-weight (<25 BMI) and overweight (25 BMI >).

Overweighed subjects presented greater significant values of isometric hand strength, probably explained due to the larger body mass, consequent with previous studies comparing the strength of obese and non-obese subjects of either upper [47] and lower body [48] strength. In addition, overweighed subjects present greater marksmanship values evaluated at all moments, reinforcing the relationship between hand strength and shooting marksmanships [49].

However, the cardiovascular response of overweighed subjects was significantly higher during both physical stress protocols, explained due to inferior cardiovascular performance, since for the same stimuli and intensity greater cardiovascular output is needed compared to normal-weight subjects.

Nevertheless, during shooting actions their HR was similar to the normal-weight group, decreasing to HR values related with no negative effect on fine motor skills. In addition, RPE was also higher in overweighed subjects after both protocols, suggesting greater effort and exposing inferior fitness, explained due to worst physical conditioning, or the fact that being overweight is an added organic stressor 50. In this line, previous authors correlated larger BMI with reduced cardiovascular output and lower performance, showing greater sympathetic, stress, and RPE baseline values [51], supporting our present data.

CONCLUSIONS

An endurance stress protocol produced a higher cardiovascular and perceived exertion than a resisted one, not affecting hand strength, shooting heart rate, and marksmanship. Females presented lower hand strength and marksmanship while higher rated of perceived exertion and heart rate during the endurance and resisted stress protocols than males.

Overweight participants presented higher heart rates during both physical stress protocols, but higher hand strength and marksmanship while similar shooting heart rates than normal-weight participants.

Limitations of the study practical applications

The small number of subjects is one of the main limitations of the present study, however, there were no more available subjects at the moment. A second limitation was the lack of evaluation of hormones such as testosterone, alpha-amylase, and cortisol to control the hormonal stress response. These limitations were subjected to financial and technological lack.

Practical applications

The information of the present research could be used for specific training, allowing further individualization of the training stimulus according to gender, anthropometric and experience characteristics. In addition, soldiers, police, and other security crops, as well as those sport modalities in which shooting is present, for example, biathlon, could potentially benefit from this information.

Effect of pharmacist's patient education on patient compliance in the southeast of Iran: A quasi-experimental study

Fatemeh Izadpanah[1], Dariush Rigi[2], Mahdi Afshari[3], Mandana Moradi[4]

Abstract: *Background: As an essential part of the treatment chain and also the link between physicians and patients, pharmacists play a major role in optimizing drug administration. Compliance with a therapeutic regimen is necessary for therapeutic success, while non-adherence can lead to disease progression and eventually treatment failure. This study aimed to evaluate the impact of pharmacist's patient education on different parameters of patient compliance.*

Results: The results showed the patients receiving the intervention compared to the control group, were significantly more adherence to the correct drug use dose (p = 0.016), time of use (p = 0.018), treatment duration (p =0.001), and frequency (p = 0.049).

Conclusions: This study indicates that detailed patient counseling at pharmacies can positively influence different parameters of patients' adherence.

Keywords: *pharmacists; monitoring drug therapy; disease management*

BACKGROUND

Medication adherence knowledge plays a crucial role in treatment success. Pharmacists' scientific skills to teach required information about drug administration, interactions, side effects storage is crucial to improve patient adherence and so treatment success [1, 2]. Patient education by pharmacists can decrease drug therapy problems arising from inappropriate drug administration or prescriptions and decrease overall health care costs [3-5]. Over the past 30 years, the scope of medication therapy management, as well as pharmaceutical care, focused on more specialized and patient-centered care through a more effective pharmacist-patient relationship [4]. Pharmacists also are one of the most important parts of rational drug use based on the World Health Organization (WHO) definition [6] and decreasing its burden [5, 7, 8]. On the other hand, inappropriate administration of antimicrobials may lead to drug resistance and treatment failure that is one of the most challenging problems today [7, 8]. Studies show that one of the main causes of irrational drug use is considering pharmacists only as drug distributors and ignoring their potential role as consultants and educators [9, 10]. In 2003,

the WHO identified poor patient adherence to achieve all therapeutic goals as a major cause of treatment failure [4]. Although the impact of medication counseling by pharmacists on patient treatment outcome, has not been investigated truly, it has been shown that community pharmacists have a great impact on improving patient adherence especially in patients suffering from chronic diseases as well as improving overall community health [1, 11, 12]. Thus, growing an effective patient-pharmacist relationship is a key factor to optimize medication use and it seems necessary to focus on pharmacists consulting skills and supportive laws [13]. In the present study, considering the undeniable role of pharmacists in patient education and improving their compliance with therapeutic regimen, we evaluated the impact of medication consultation on the appropriate use of medication by patients referring to community pharmacies in Zabol city, southeast of Iran at 2019.

METHODS

Design and participants

This quasi-experimental study was conducted on 56 newly diagnosed patients in one governmental hospital (xxxx) affiliated to XXXX University of Medical Science in the southeast of XXXX from March 10, 2019, to August 30, 2019. Participants were selected using a simple random method and distributed to intervention and control groups. Patients were defined new to therapy if they had no evidence of filling prescriptions with their current medications during the past 6 months. Considering the mean scores for treatment belief for two control (5.04 ± 3.4) and intervention (2.52 ± 2.64) groups in pilot research, the type I error of 0.05, the test power of 0.80 as well as 20% sample loss, the required sample size was estimated as of 23 people in each group.

Intervention

The intervention group received their medications with written instructions on drug packages as well as face-to-face education by pharmacists mainly about dosage, regimen, and length of treatment of each drug in their prescriptions. In the control group received their medications only with routine written instructions on each drug package. Each patient in the control group who had a question that needs further education was excluded from the study.

Instruments

The patient’s demographic information was included in data collection forms. Two separate questionnaires designed based on literature review and pilot tested. Patients or family caregiver received the first questionnaire, before collecting their prescriptions and the second one 14 days after. The first questionnaire consisted of four questions about their risk of non – adherence [14] as well as eight questions about their belief about prescribed medicines [15]. The second one consisted of five questions about the patient's practice (correct dose, time, frequency, and therapeutic course) about each of their prescribed medications. The investigator who reviewed patient medications after 14 days and filled out the second questionnaire did not know whether patients are in sample or control groups. The face and content validity of the questionnaire was determined by collecting the six experts' opinions. The questionnaires were then distributed to 20 people in a pilot form. The final questionnaires were designed after identifying the bugs and fixing them. To assess the reliability of the questionnaire. Belief about prescribed medication score and total performance score was obtained from the sum of scores of the relative questionnaires.

Statistical analysis

Statistical analysis of the present data was carried out using an independent t-test and chi-square test using SPSS software (version 21). P-value < 0.05 was considered as significant.

Ethical consideration

The study protocol was approved by the XXXX University of Medical Sciences Ethics Committee (code: XXXXXX) and patients provided written informed consent before participating in the study.

RESULTS

After considering the exclusion criteria, 56 patients were eligible to enroll in this study, 28 patients in both the intervention and control group. Our participants consisted of 45 (80.4%) male and 11 (19.6%) female 7.1% of whom were uneducated. Their ages ranged between 15 - 75 years with the mean age of 33.46 (14.20) years. The mean scores of the patient’s primary risk of non-adherence and belief about prescribed medicines were 5.27 (0.92) and 23.89 (3.08) respectively.

There was no statistically significant difference between intervention and control groups in terms of age (p = 0.640), gender (p = 0.313), level of education l (p = 0.968), belief about prescribed medicines (p=0.180) and risk of non-adherence (p = 0.679) (Table 1).

Table 1: Demographic characteristics of sample and control groups

		Control	Sample	P-value
Age		30.03 (18.09)	24.43 (15.75)	0.640
Sex	Male	21 (75%)	24 (85.7%)	0.313
	Female	7 (25%)	4 (14.3)	
Level of education	Uneducated	2 (7.1%)	2 (7.1%)	0.968
	Under high school diploma	9 (32.2%)	7 (25%)	
	High school diploma	13 (46.4%)	14 (50%)	
	College degree	1 (3.6%)	3 (10.7%)	
	Bachelor degree	3 (10.7%)	2 (7.1%)	
Belief about prescribed medicines		24.11 (2.92)	23.68 (3.27)	0.679
Risk of non-adherence		5.11 (0.91)	5.43 (0.92)	0.180

Our results showed that patients receiving face-to-face education were significantly more adherent to the correct dose (p = 0.016), exact time (p=0.018), frequency of drug administration (0.049), and completing the therapeutic course (p <0.001), compared to the control group (Table 2).

Table 2: Comparison of patient's adherence to correct dose, time, frequency and completing the therapeutic course in control and sample groups

	Control No (%)	Sample No (%)	P-value
Correct dose	16 (57.1%)	25 (89.3%)	0.016
Correct Time	7 (25%)	17 (60.7%)	0.018
Correct frequency	14 (50%)	22 (78.6%)	0.049
Completing therapeutic course	3 (10.7%)	19 (67.9%)	<0.001

Finally, 100 % of the patients in the intervention group and 17.9% of the control group were satisfied with the pharmacist's services (p < 0.001) (Table 3).

Table 3: Comparison of participants' satisfaction in control and sample groups.

Satisfaction		Control	Sample	P-value
Agree	No (%)	5 (17.9)	28 (100)	<0.001
No Idea	No (%)	7 (25)	0 (0)	
Disagree	No (%)	16 (57.1)	0 (0)	
Total	No (%)	28 (100)	28 (100)	

DISCUSSION

Pharmacists as an essential part of the treatment chain and also the link between physicians and the patients play major roles in health care systems [16]. Studies have shown that pharmacists can improve patient adherence and the rate of treatment success. Noncompliance can lead to irrational drug use, expansion of drug therapy costs, the prolongation of therapeutic courses, and adverse drug reactions. In this study, we evaluated the impact of patient education by pharmacists in different aspects of patient compliance and concluded its positive impacts. Our study population is divided into two intervention and control groups. The intervention group received medication counseling especially about dose, time, and frequency of drug administration and duration of therapy besides routine written instructions on drug packages that were consistent in both groups. We observed that although sample intervention groups were not significantly different in terms of demographic data, risk of non-adherence, and belief about their prescribed medication but their final behavior about their prescribed medications were completely different. Adherence to the correct dosage, timing, frequency, and therapeutic course was significantly higher in patients receiving drug education by pharmacists. They were also more satisfied with the pharmacist's services. These results were in agreement with the previous results of previous studies [17-21].

They proved positive impacts of patient counseling at the pharmacies on accomplishing therapeutic goals, reducing adverse drug reactions, and administration drug errors in their researches. Our findings showed that a relatively high number of patients who did not receive counseling did not properly follow their treatment course, which can lead to therapeutic failure and its related complications. Especially, when patients are on antibiotics, non-adherence can lead to drug resistance and finally affect both patients and society. The small sample size was one of our limitations in this study, besides if we could monitor a patient's performance more often, we would be able to provide more accurate results and lower possible bias. One of the strengths of this study was that patients with a history of the same disease were excluded from the study so that their previous experiences did not affect the final results.

CONCLUSIONS

It can be concluded that detailed patient counseling by pharmacists, can positively influence patients' adherence. In this regard, it seems necessary to focus on communicating and counseling skills of pharmacists and even motivational tools as counseling fees.

Efficacy and safety of Ombitasvir/Paritaprevir/Ritonavir+ Dasabuvir and Ribavirin in patients with compensated HCV cirrhosis

Georgiana C. Crişu[1,2], Florentina Ioniţă-Radu[3,4], Raluca S. Costache[2,3], Vasile D. Balaban[2,3]; Petrut Nuţă[3], Victor Stoica[2,5], L. Oana Vutcan[5], Ion Ştefan[2,3], Florica Mali Năftănăilă[6], Mariana Jinga[2,3]

Abstract: *Background and aim: Ombitasvir/Paritaprevir/Ritonavir+Dasabuvir in association with ribavirin was the only interferon-free regimen available in 2015 in Romania for compensated HCV cirrhosis. The aim of our study is to reveal our experience with interferon-free therapy in compensated HCV cirrhosis.*

Materials and methods: We conducted a multicenter prospective study including 90 patients with compensated (Child-Pugh A) HCV cirrhosis treated with Ombitasvir/Paritaprevir/Ritonavir + Dasabuvir and Ribavirin regimen for twelve weeks. The HCV infection was diagnosed using clinical, biological, and FibroMax tests. Each patient had follow-up visits at four, eight, twelve and twenty-four weeks after the initiation of the treatment.

Results: 44 (49% of) patients were female and 46 (51 % of) were male. The mean age of patients in the study was 61 years old. All the patients had HCV genotype 1b infection. 22 patients were naive and 68 had previous antiviral therapies based on pegylated IFN-α and ribavirin. At the initiation of treatment 64 (71%) of patients had cytolysis, 38 (42%) had thrombocytopenia, 19 (21%) patients had hyperbilirubinemia and 11 (12%) patients had anemia. It was noticed a decreasing of cytolysis, only 10% of 64 patients still having cytolysis after four weeks of treatment. One patient (1%) died after four weeks of treatment by complications of cirrhosis. 89 (99%) of patients had a virologic response (VR) at the end of treatment (EOT) and sustained virologic response (SVR) twelve weeks after the last dose administration.

Conclusion: The most common side effect among the patients in the study group was anemia (47% cases). Cytolysis disappeared after four weeks of treatment in 61% of patients. The interferon-free combination treatment was safe and highly effective in compensated HCV cirrhosis.

INTRODUCTION

The World Health Organizations estimates that there are 150 million people infected with hepatitis C virus [1].

Hepatitis C virus (HCV) affects individuals worldwide with a high degree of morbidity and mortality. Chronic HCV can lead to cirrhosis, hepatocellular carcinoma, the need for transplantation and death. The annual incidence of hepatocarcinoma in patients with HCV cirrhosis is between 1% to 7% [2, 3, 4, 5]. Genotype -1 is the most common HCV genotype from all the 7 genotypes [6]. Genotype-1b is the most prevalent HCV subtype in Europe, Central America, the Middle, and Asia [7].

Therapy with pegylated interferon and ribavirin for 12 weeks to 72 weeks was associated with low SVR (only 60% of them achieved sustained virologic response) and with adverse events [8, 9]. It can be a challenge for patients with cirrhosis to achieve SVR.

Sustained virologic response is defined as undetectable HCV-RNA at 12 weeks, after the end of treatment (EOT) and it is associated with improved survival and reduced risk of HCC development in patients with cirrhosis [10,11,12].

New IFN-free direct- acting antiviral (DAA) therapies have greatly improved SVR rates in patients with cirrhosis [13, 14, 15, 16, 17]. In most regimens for maximizing the SVR rates in patients with cirrhosis, it was required the addition of ribavirin [18, 19].

The available DAA are classified according to the viral target protein as NS3/4A protease inhibitor, NS5B polymerase inhibitors (including non-nucleoside and nucleoside inhibitors) and NS5A inhibitors [20].

Direct-acting antiviral agents were approved for the first time in 2011 for the treatment of hepatitis C. Although the addition of the NS3/4A protease inhibitors boceprevir, telaprevir or simeprevir to pegylated interferon and ribavirin regimens increased SVR rates in patients with genotype-1 infection efficacy rates have remained low in patients with cirrhosis [21, 22, 23, 24, 25].

The regimen containing ombitasvir/paritaprevir/ritonavir and dasabuvir with or without ribavirin was approved by the European Medicine Agency and/or the Federal Drug Administration for the treatment of patients without and with cirrhosis Child-Pugh-Turcotte class A.

Ombitasvir (OBV) is an NS5A inhibitor co-formulated with NS3/4A protease inhibitor paritaprevir (PTV), and the pharmacokinetic enhancer ritonavir which increases peak through drug allowing for once daily PTV dosing exposure [26,27]. Dasabuvir is a non-nucleoside NS5B polymerase inhibitor. This 3-DAA regimen with or without ribavirin (RBV) is approved in many countries to treat HCV genotype-1 infection.

Most of prospective phase II and III trials included only a few patients with cirrhosis.

The regimen Ombitasvir/paritaprevir/ritonavir and dasabuvir were evaluated in two studies in patients with compensated HCV cirrhosis. One study-TURQUOISE II trial, an open-label phase III trial evaluated the 3D regimen with ribavirin for 12 weeks vs 24 weeks in patients with compensated HCV cirrhosis. The other study – TURQUOISE III phase III b, open-label study evidenced if it could be achieved a good SVR without ribavirin at 3D regimen in 60 patients with compensated HCV cirrhosis. Ombitasvir/paritaprevir/ritonavir + dasabuvir with ribavirin became available in Romania for compensated HCV cirrhosis from November 2015 to November 2017 as the only interferon-free regimen.

We reported the results of a prospective study designed to asses the efficacy and safety of the regimen ombitasvir/paritaprevir/ritonavir+dasabuvir with ribavirin in patients with compensated HCV cirrhosis genotype-1b, with or without experienced pegIFN/RBV.[28, 29, 30].

PATIENTS AND METHODS

Study Patients

We conducted a multicenter prospective study including 90 patients with compensated (Child-Pugh A) HCV cirrhosis treated with Ombitasvir/Paritaprevir/Ritonavir+Dasabuvir and Ribavirin regimen for 12 weeks. Patients were diagnosed by clinical, biological, and FibroMax tests.

Patients 18 years or older were eligible for the therapy if they had HCV genotype-1b infection for at least 6 months prior to screening, an HCV RNA > 15 UI/ml. Cirrhosis had to be documented by liver biopsy (Metavir score >3) or FibroMax (available within 3 months before therapy) and a Child-Pugh Turcotte score 5 or 6.

We included in the treatment-naive patients or those with prior exposure to PegIFN/RBV based therapy.

Decompensated cirrhosis and hepatocarcinoma were exclusion criteria.

Each patient had follow-up visits at four, eight, twelve and 24 weeks after treatment initiation. Biological tests included: hemoglobin, ALT, AST, platelets, total bilirubin, serum albumin, INR. We defined anemia as Hb<12 g/dl in women and Hb< 13 g/dl in men. Cytolysis was defined as values of ALT or AST > at least 2 times upper limit of normal. Hyperbilirubinemia was defined as a level of bilirubin > than 1.2 mg/dl. HCV RNA level in blood was evaluated at baseline, end of treatment (EOT) and 12 weeks after EOT. Undetectable HCV RNA was defined as a viral load <15 UI/ml, assessment by PCR. Virological response (VR) was defined as undetectable HCV RNA at EOT and sustained virologic response (SRV) as undetectable HCV RNA at 12 weeks after EOT.

Study design

All patients received the therapy for 12 weeks. Co-formulated OBV/PTV/r was administered once daily (25/150/100 mg) and DSV 250 mg twice daily. Patients were followed up at four, eight, twelve, and twenty-four weeks after treatment initiation.

Written informed consent was obtained from each patient, and the study protocol conformed to the ethical guidelines of the 1975 Declaration of Helsinki.

Efficacy, safety and pharmacokinetic assessments

Plasma samples were collected at screening and at each study visit and HCV RNA levels were determined processed by real-time polymerase chain reaction using the COBAS TaqMan HCV version 2.0 (Roche Molecular Diagnostics). Efficacy was assessed by the percentage of patients with SVR12, defined as an HCV RNA below the lower limit of quantitation of 25 UI/ml and a lower limit of detection of 15 UI/ml after the last dose of study drug.

The primary efficacy endpoint was SVR12 (HCV RNA level <25 UI/ml 12 weeks after the last dose of study drug. The rates of SVR 4 weeks after the end of treatment (SVR4) and rapid virologic response (RVR; HCV RNA level <25 UI/ml) were also determined.

Treatment adverse events were collected from the start of study drug administration until 30 days after the last dose. Laboratory tests and clinical parameters were assessed during the study. The severity of the adverse events and their relationship with treatment were evaluated by the investigator.

Statistical Analysis

Number and percentage of patients in different categories are reported. Categorical variables included in the analysis were: sex, the previous treatment regimen. Continuous variables included were: age, cytolysis, thrombocytopenia, anemia, hyperbilirubinemia.

Results

Baseline Patient Demographics and Characteristics.

We screened patients from November 2015 to August 2016 at five sites in Bucharest. 90 patients were enrolled and received the study drug. The majority of patients had prior treatment experience with PegIFN/RBV. 22 patients were treatment-naive and 68 patients had experienced Peg/IFN/RBV.

Demographics and clinical characteristics are presented in Table 1 and Table 2.

Table 1. Baseline demographic characteristics

Parameter	**Patients** (n=90) n/%
Age (years)	65
Female gender	44 (49)
Male gender	46 (51)
Treatment naïve	22 (24)
Treatment experienced	58 (76)

Table 2. Baseline clinical characteristics

Parameter	**Patients** (n=90) n/%
Cytolysis	64 (71)
Anemia	11 (12)
Hyperbilirubinemia	19 (21)
Thrombocytopenia	38 (42)

Efficacy Outcomes

89-99% of patients completed 12 weeks of treatment with ombitasvir/paritaprevir/ritonavir, dasabuvir and ribavirin. After 12 weeks of treatment, 99% of patients achieved SVR 12 (89/90, 95% CI, 80%-99.9%) (Table 3). One patient died after four weeks of treatment.

Another patient (female, 60 years old, known with diabetes mellitus) gave up ribavirin after four weeks of treatment because of severe anemia (level of hemoglobin was 6 g/dl). We hadn't any virologic failure.

Table 3. Efficacy and safety of DAA regimen

Parameter	**Patients** (n=90) n/%
SVR	89 (99)
Anemia	42 (47)
Death	1 (1)

Improvement in laboratory assessments

At baseline 71 % (64) of patients had cytolysis and 42 % (38) had thrombocytopenia (Table 4).

Only 10% (9) of patients had cytolysis at the end of treatment. Thrombocytopenia was improved at the end of treatment, thus it was seen at only 26% of patients.

Table 4. Characteristics of patients at the end of treatment

Parameter	**Patients** (n=90) n/%
Cytolysis	9 (10)
Anemia	2 (47)
Hyperbilirubinemia	6 (40)
Thrombocytopenia	3 (26)

Safety outcomes

Most of the patients had adverse events and one patient died after four weeks of treatment. Anemia was the most frequent adverse event. At baseline only 12% of patients had anemia, but at the end of treatment the number of patients who developed anemia was increasing up to 47%. Another laboratory abnormality was hyperbilirubinemia. At the beginning of the treatment, only 21% of patients presented a high level of bilirubin. At the end of treatment, hyperbilirubinemia was seen in 40% of patients. One patient developed severe anemia (hemoglobin level was 6 g/dl) after four weeks of treatment and thus ribavirin was stopped.

DISCUSSION

Patients with HCV infection and cirrhosis are at the highest risk for hepatocarcinoma, decompensation and, mortality. In this study treatment with OBV/PTV/r, DSV and RBV had the SVR 12 rate of 99% in HCV genotype-1b infected patients with compensated cirrhosis. Treatment was well tolerated with a low rate of severe AE.

The most side effect among the patients in the study group was anemia in 47% cases. Cytolysis disappeared after four weeks of treatment at 61 % of patients. 89 of 99 patients (99%) had sustained virologic response at twelve weeks. One patient died after four weeks of treatment (1%). The treatment was safe and effective in compensated HCV cirrhosis.

In conclusion the 12 week 3-DAA regimen of OBV/PTV/r, DSV and RBV achieved the SVR 12 rate of 99% experienced and naive treatment patients with compensated cirrhosis HCV genotype-1b.

SYSTEMATIC REVIEW

Efficacy and tolerability of antibiotic augmentation in schizophrenia spectrum disorders – A systematic literature review

Octavian Vasiliu[1], Daniel Vasile[2], Victor A. Voicu[2,3]

Abstract: *Background: A large number of augmentation agents have been tried in patients with schizophrenia spectrum disorders, because negative and cognitive symptoms are difficult-to-treat with current pharmacological agents, and because the high percentage of treatment-resistant cases requires new therapeutic solutions. Inflammation is one of the supposed pathophysiological mechanisms in schizophrenia; therefore, antibiotics have been explored as add-on agents. No systematic review or meta-analysis about the efficacy of antibiotics in psychotic disorders has yet been conducted. Objectives: To assess if the use of antibiotics as add-on to current antipsychotic treatment may improve core symptoms of schizophrenia spectrum disorders, global clinical status, overall functionality, and if this augmentation strategy is well tolerated. Methods: A systematic literature review was conducted, including papers published between 1980 and 2018, which have been found in the main electronic databases (PubMed/MEDLINE, CINAHL, NCBI, Embase, Thomson Reuters/Web of Science). The keyword search strategy was formulated using the following paradigm: „schizophrenia spectrum disorders"/ „schizophrenia"/ „schizo-affective disorder"/ „schizophreniform disorder", AND „antibiotics"/ all the names of currently marketed antibiotics classes. This review was registered to PROSPERO database with the protocol number CRD42019119152. Results: Based on reviewing the selected trials regarding the efficacy of antibiotics over core symptoms of schizophrenia, only two agents were detected – minocycline and D-cycloserine. Minocycline as add-on to antipsychotic treatment was associated with mixed results, while regarding the efficacy of d-cycloserine either no significant difference, or superiority to placebo over negative and cognitive symptoms was reported. Minocycline had an overall effect over the clinical impression that was not distinguishable from placebo, although there was one trial supporting the efficacy of this antibiotic. The impact of minocycline over the global functioning when added to antipsychotic in patients with schizophrenia was mixed, with one positive and one negative trial (moderate to high quality designed trials). D-cycloserine had no significant impact over global clinical status or patients' overall functionality. Conclusion: From all the data reviewed and hierarchized resulted that larger trials are needed in order to confirm the efficacy of antibiotics as add-on to antipsychotics over negative and cognitive symptoms of schizophrenia spectrum disorders.*

Keywords: *antibiotics, augmentation strategy, negative symptoms, cognitive symptoms, tolerability, schizophrenia spectrum disorders*

BACKGROUND

Negative and cognitive symptoms are extremely challenging for clinicians who are treating patients with schizophrenia, and these clinical phenomena are important to approach because they are related to functional prognosis, real-world performance and quality of life. If currently marketed antipsychotics can control positive, behavioral and sometimes affective symptoms of schizophrenia, when negative and cognitive symptoms are analysed

longitudinally, the results are still disappointing [1]. The prevalence of treatment-resistant schizophrenia is estimated to be approximately 30% (range 10-45%) [2] and an important number of patients have „ultra-resistant" schizophrenia, defined as resistance to clozapine [3]. In all these cases, a significant number of psychotic symptoms persist, although several trials of antipsychotics have been conducted for enough time in adequate doses [3]. Treatment-resistant cases require additional therapeutic agents, and a large number of solutions have been formulated without reaching a consensus (except for clozapine, but as previously mentioned, there are cases resistant even to this second-line atypical antipsychotic).

A significant number of symptoms detected in treatment-resistant patients are based on cognitive deficits [4], and the N-methyl-D-aspartate (NMDA) receptor hypofunction hypothesis attempts explaining why antipsychotic treatment may attenuate the striatal dopaminergic dysfunction without having an influence over the prefrontal cortex in treatment-resistant cases [5]. Negative symptoms have been demonstrated to explain the highest part of variation in disease severity in treatment-resistant schizophrenia, and these symptoms mediated the effects of verbal fluency dysfunctions and high-level neurological soft signs on disease's severity [6].

Many treatments from a large area of pharmacological, psychotherapeutical and other somatic approaches (e.g., deep brain stimulation) have been investigated for the management of negative and cognitive symptoms of schizophrenia, but there is no first-line therapy yet established for these cases. Atypical antipsychotics used at the lowest dose necessary to control positive symptoms, antidepressants as add-on agents, and cognitive-behavioral therapy have been suggested with limited efficacy in schizophrenia with prominent negative symptoms [7]. Many different pharmacological targets have been suggested for addressing cognitive symptoms in schizophrenia, from D1-agonists to glycine site agonists, and from type A gamma-amynobutyric acid (GABA-A) receptors agonists to alpha7-nicotinic receptors partial agonists, but without significant effects [8-10].

Antibiotics have been explored in clinical practice not only for their anti-microbial properties, but also for their neuroprotective and antiinflammatory effects. As schizophrenia has been associated with increased levels of circulating pro-inflammatory markers and microglial activation in both animal and human studies, researchers have become increasingly interested in the therapeutic potential of antibiotics [11]. Many β-lactams antibiotics have been associated with increased glutamate type 1 transporter (GLT1) expression in animal models, which can lead to a prevention of toxic neuroexcitation by excessive glutamate transmission [12]. Macrolides may confer neuroprotection against ischemic damage following cerebral ischemia without cerebral blood flow impairments [13]. Doxycycline was proven to prevent amyloid-β toxicity both in vivo and in vitro in a Drosophila melanogaster model of Alzheimer disease [14]. Minocycline is a second generation, semi-synthetic tetracycline that has been associated with neuroprotective, anti-inflammatory and anti-apoptotic properties, which also can inhibit proteolysis, angiogenesis and tumour metastatis [15-17]. D-cycloserine is not only an antituberculosis agent, but also a glycine site partial agonist studied for its properties to enhance neuroplasticity in schizophrenia [18].

While many data on the effects of antibiotics over neuroplasticity are derived from animal models, information on the clinical impact of these pharmacological agents in patients diagnosed with schizophrenia spectrum disoders are contradictory [18-22].

The objectives of this systematic literature review are (1) the evaluation of antibiotics efficacy as add-ons in the management of the core symptoms of schizophrenia spectrum disorders, global clinical status, overall functionality, and (2) to verify if this augmentation strategy is well tolerated. These objectives are considered of clinical interest for psychiatrists, but they also may be useful for researchers oriented on finding new, non-dopaminergic-based treatments for psychotic disorders.

METHODS

This systematic review is based on the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement (Table 1) [23]. The protocol of this review was registered in the PROSPERO with the protocol number CRD42019119152 [24].

2.1. Outcomes

The primary outcome for this review was the efficacy of any antibiotic in decreasing symptoms severity in schizophrenia spectrum disorders. We considered the impact of these agents over positive, negative, cognitive, behavioral, and/or affective dimensions of psychosis, as determined by validated psychometric scales for this specific pathology.

The secondary outcomes were (a) tolerability of antibiotics, assessed by either subjective reports or validated instruments, (b) general functionality of patients, and (c) global clinical status, assessed by structured instruments.

2.2. Search strategy

A keyword search strategy was formulated using the following paradigm: „schizophrenia spectrum disorders”/„schizophrenia”/„schizo-affective disorder”/„schizophreniform disorder”, AND „antibiotics”/all the names of currently marketed antibiotics classes. Electronic databases searched were Medline (PubMed), Embase, Cumulative Index to Nursing and Allied Health Literature (CINAHL), National Center for Biotechnology Information (NCBI), and Thomson Reuters/Web of Science. Papers included in the references of the analyzed articles were also reviewed, and their results were included if the quality of research corresponded to the pre-defined inclusion and exclusion criteria. We selected clinical trials that were published in any language, between January 1980 and January 2019.

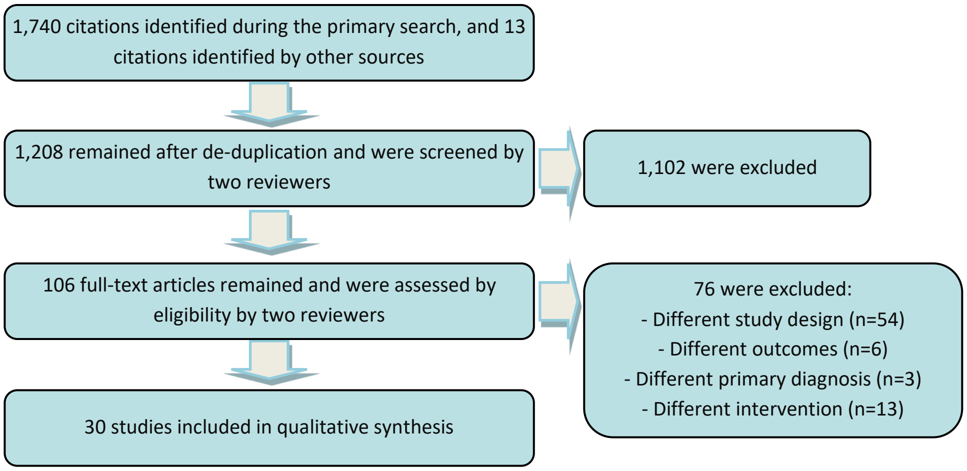
Table 1: PRISMA-P 2015 Checklist [25]

Section/topic	#	Checklist item	Information reported		Line number(s)
			Yes	No	
ADMINISTRATIVE INFORMATION					
Title					
Identification	1a	Identify the report as a protocol of a systematic review	☒	☐	92-94
Update	1b	If the protocol is for an update of a previous systematic review, identify as such	☐	☐	Not applicable
Registration	2	If registered, provide the name of the registry (e.g., PROSPERO) and registration number in the Abstract	☒	☐	94
Authors					
Contact	3a	Provide name, institutional affiliation, and e-mail address of all protocol authors; provide physical mailing address of corresponding author	☒	☐	Title page
Contributions	3b	Describe contributions of protocol authors and identify the guarantor of the review	☒	☐	138-150
Amendments	4	If the protocol represents an amendment of a previously completed or published protocol, identify as such and list changes; otherwise, state plan for documenting important protocol amendments	☐	☐	Not applicable
Support					
Sources	5a	Indicate sources of financial or other support for the review	☒	☐	146-148
Sponsor	5b	Provide name for the review funder and/or sponsor	☐	☐	Not applicable
Role of sponsor/funder	5c	Describe roles of funder(s), sponsor(s), and/or institution(s), if any, in developing the protocol	☐	☐	Not applicable
INTRODUCTION					
Rationale	6	Describe the rationale for the review in the context of what is already known	☒	☐	45-89
Objectives	7	Provide an explicit statement of the question(s) the review will address with reference to participants, interventions, comparators, and outcomes (PICO)	☒	☐	135-136, Table 1
METHODS					
Eligibility criteria	8	Specify the study characteristics (e.g., PICO, study design, setting, time frame) and report characteristics (e.g., years considered, language, publication status) to be used as criteria for eligibility for the review	☒	☐	124-133, Table 1
Information sources	9	Describe all intended information sources (e.g., electronic databases, contact with study authors, trial registers, or other grey literature sources) with planned dates of coverage	☒	☐	124-133
Search strategy	10	Present draft of search strategy to be used for at least one electronic database, including planned limits, such that it could be repeated	☒	☐	104-111
STUDY RECORDS					
Data management	11a	Describe the mechanism(s) that will be used to manage records and data throughout the review	☒	☐	138-150

Selection process	11b	State the process that will be used for selecting studies (e.g., two independent reviewers) through each phase of the review (i.e., screening, eligibility, and inclusion in meta-analysis)	☒	☐	138-150
Data collection process	11c	Describe planned method of extracting data from reports (e.g., piloting forms, done independently, in duplicate), any processes for obtaining and confirming data from investigators	☒	☐	138-150
Data items	12	List and define all variables for which data will be sought (e.g., PICO items, funding sources), any pre-planned data assumptions and simplifications	☒	☐	138-150, Table 1
Outcomes and prioritization	13	List and define all outcomes for which data will be sought, including prioritization of main and additional outcomes, with rationale	☒	☐	96-102
Risk of bias in individual studies	14	Describe anticipated methods for assessing risk of bias of individual studies, including whether this will be done at the outcome or study level, or both; state how this information will be used in data synthesis	☒	☐	143-147
DATA					
Synthesis	15a	Describe criteria under which study data will be quantitatively synthesized	☐	☒	
	15b	If data are appropriate for quantitative synthesis, describe planned summary measures, methods of handling data, and methods of combining data from studies, including any planned exploration of consistency (e.g., I^2, Kendall's tau)	☐	☒	
	15c	Describe any proposed additional analyses (e.g., sensitivity or subgroup analyses, meta-regression)	☐	☒	
	15d	If quantitative synthesis is not appropriate, describe the type of summary planned	☒	☐	156-164
Meta-bias(es)	16	Specify any planned assessment of meta-bias(es) (e.g., publication bias across studies, selective reporting within studies)	☐	☒	
Confidence in cumulative evidence	17	Describe how the strength of the body of evidence will be assessed (e.g., GRADE)	☒	☐	52-57

This checklist has been adapted for use with protocol submissions to Systematic Reviews from Table 3 in Moher D et al: Preferred reporting items for systematic review and meta-analysis protocols (PRISMA-P) 2015 statement. Systematic Reviews 2015 4:1

Figure 1: Results of the PRISMA-based search paradigm



1,740 citations identified during the primary search, and 13 citations identified by other sources
1,208 remained after de-duplication and were screened by two reviewers
1,102 were excluded
106 full-text articles remained and were assessed by eligibility by two reviewers
76 were excluded:
- Different study design (n=54)
- Different outcomes (n=6)
- Different primary diagnosis (n=3)
- Different intervention (n=13)
30 studies included in qualitative synthesis

2.3. Inclusion and exclusion criteria

Studies were eligible for inclusion if they were randomized/non-randomized, open label, single blind or double blind, with or without active comparator, prospective/retrospective trials. These studies could be controlled with placebo, any other active drug, or usual care, and they must have specified diagnosis criteria for the explored clinical entity/entities. All patients included in these trials were over 18 years old at the initial visit, and no superior limit of age was established. Validated instruments for evaluation of the efficacy of the investigational product should be used at baseline and at least at end-point, e.g. Positive and Negative Syndrome Scale or Brief Psychiatric Rating Scale.

Only full-text articles were eligible for analysis, but if abstracts with outcomes corresponding to those defined by us were found, authors of the respective works were contacted to provide full-text of their papers. No limitation about the duration of the follow-up was included as a criterion of trials selection. A more detailed presentation of the inclusion and exclusion criteria is emphasized in Table 2.

Table 2: Inclusion and exclusion criteria

Operational criteria	Inclusion criteria	Exclusion criteria
Population	Minimum age of inclusion in the selected trial was specified as being 18, according to the study protocol. No superior age limit was specified. The main diagnosis was schizophrenia, schizo-affective disorder, schizophreniform disorder, or any combination of these entities. Diagnosis based on standardized criteria (DSM, ICD, or other compatible psychiatric classifications). Patients with resistant forms of schizophrenia were included (defined by resistance to at least 2 antipsychotic agents, each administered for a minimum duration and dosage, currently presenting symptoms of a minimum duration and severity determined by a standardized rating scale, and moderate or worse functional impairment) [15].	Patients with age under 18, except for cases where statistical procedures allowed for a separate evaluation of the adult vs. child population. The presence of severe somatic or psychiatric co-morbidities with significant impact over cognition, disposition, behavior, and overall functionality. The presence of infectious diseases, which require antibiotic therapy, as co-morbid or main diagnoses. Any co-morbidities which can create confusions in the domain of antibiotics efficacy over psychotic symptoms, either organic diseases (e.g., infections), or psychiatric (e.g., disorders induced or related to drugs or general medical conditions). Neurocognitive co-morbities were not allowed.
Intervention	Antibiotics used as add-on to any antipsychotic agent, either typical or atypical. Antibiotics from any class that is currently marketed, with no limitations related to the dosing regimen, adverse events profile, or any pharmacokinetic/pharmacodynamic property. The effects of the intervention over targeted symptoms of schizophrenia spectrum disorders were quantified using at least one validated instrument.	Trials controlled by psychotherapy only. Studies controlled by non-pharmacologic and non-psychotherapy interventions, e.g., deep brain stimulation, electroconvulsive therapy, transcranian magnetic stimulation. Over-the-counter products or dietary supplements as add-on or active comparators. Investigational pharmacologic agents used in phase II or III clinical trials. Administration of more than one antibiotic at a time.
Environment	Hospitals, day care, special care, permanent care, or intermediate care units. Both in-patient and out-patient regimen. A caregiver who is able to report on the patient's evolution under treatment and therapeutic adherence was considered optional.	Correctional environments. Unspecified environment.
Primary and secondary variables	Changes in psychotic symptoms (positive, negative, cognitive, behavioral, and/or dispositional) were evaluated by trained clinicians. Evaluation of the drugs tolerability, and patients overall functionality and global clinical status was also monitored. Studies were allowed to entered the analysis if they were focused on efficacy, tolerability, or both of these outcomes.	All trials using unspecified psychometric instruments, or only clinical observation were excluded.
Study design	Intervention was studied in randomized/non-randomized, open label, single blind, or double blind, with or without active comparator/placebo, prospective/retrospective trials. No limitation about the duration of the treatment was established. Only peer-reviewed studies were included.	Studies with unspecified or insufficiently specified design. Lack of methodologic specifications regarding statistic processing of the primary/secondary variables related to the efficacy. Case reports, case series. Animal model studies. Systematic literature reviews, meta-analyses.
Language	English, French, Spanish, Russian	Any other language, except for those mentioned in the „inclusion criteria”

2.4. Data extraction and analysis

Screening was performed by two independent reviewers, and the resulted material was filtered using inclusion and exclusion criteria mentioned above. Data regarding the main outcomes, the secondary outcomes, and other relevant information about the studies were extracted into the table 3. Data extraction and quality assessment of the studies were done independently by two reviewers (OV and either VAV or DV), and if any disagreement between the two appeared and could not be resolved by consensus, the third reviewer has been consulted.

Consensus was obtained regarding the methodological quality for the included studies after each study was independently rated using the Cochrane Handbook for Systematic Reviews of Interventions - Assessing risk of bias in included studies [26]. Each study was rated as having low, moderate or high risk of bias, based on the (1) randomization procedure, (2) blinding and treatment allocation, (3) use of placebo or an active comparator, (4) methods used for evaluation of outcomes, and (5) dimension of the study group.

All included trials were reviewed critically by authors of the current article, with consideration to the bias risk. A meta-analysis could not be performed because of the heterogeneity of the methods used within the selected trials.

RESULTS

A number of 1753 citations returned after the primary search, and only 1208 remained after de-duplication. After filtering-out articles non-compatible with our predefined inclusion/exclusion criteria, and safter excluding papers for which full text could not be found or provided by authors, a number of 30 trials resulted (Figure1).

3.1. Methodological quality assessment

Among the 30 articles included in this review, a majority were of moderate quality (n=15), while the high and low quality were almost equally represented (7 and 8, respectively). Most of these trials were randomized, placebo-controlled (n=28), one open-label, and one trial had a bi-phasic design, with a single-blind, followed by a double-blind period of treatment. Only 4 trials had a sample size over 100, while 19 trials included below 50 subjects, which reduced the power of the analysis for the poor-populated trials.

Frequently encountered problems were lack of information about concealment of the randomization, and about the intent-to-treat (ITT) vs. per protocol analysis. The mean percentage of agreement between the two reviewers for each trial was 90.7% (p<0.0001) for the validity criteria.

3.2. Evaluation of primary outcome: the efficacy of antibiotics in schizophrenia spectrum disorders

The only active interventions detected by our search were D-cycloserine (n=18 trials, most of them of moderate quality) and minocycline (n=10 trials, most of them of moderate and low quality).

The efficacy of minocycline as add-on to antipsychotic treatment was investigated in two large double-blind, placebo-controlled trials (n=200 and 207, respectively) and the results were negative [27, 28]. No improvement of negative (on medium and long term), cognitive and overall psychotic symptoms (on medium term) was detected by these two studies. A small trial (n=73 subjects) evaluated the impact of minocycline as add-on to clozapine over avolition and concluded that although higher plasma levels of clozapine were detected after minocycline initiation, there was no evidence that improvement in negative symptoms can be correlated with higher level of plasma antipsychotic [29].

Another small trial (n=52) concluded that minocycline did not improve significantly psychosis factor and overall BPRS (Brief Psychiatric Rating Scale) score, neither had it a significant impact over cognitive function, except for working memory [31]. The same trial reported a significant improvement in the BPRS anxiety/depression factor in the minocycline-treated patients [31].

Regarding the positive effects of minocycline, a small trial (n=24) detected significant improvements in patients treated with this drug over the positive and negative symptoms, compared to placebo, and a protective effect of this antibiotic over the gray matter loss in fronto-temporal areas involved in the pathophysiology of schizophrenia during 12-month of active treatment [32].

Another short-term trial (8 weeks, n=43 subjects) found that SANS (Scale for the Assessment of Negative Symptoms) total score decreased significantly compared to placebo, and the negative sub-scale of PANSS (Positive and Negative Syndrome Scale) also decreased, but not significantly compared to placebo [33].

A study that evaluated 92 patients with schizophrenia treated with risperidone who received minocycline as add-on for 16 weeks reported greater improvements on SANS total scores and PANSS negative subscale versus placebo [34]. This study observed no difference between groups in cognitive performances, except for the attentional domain [34].

Table 3: Qualitative analysis of the trials selected

Intervention	Authors	Objectives	Design	Population	Outcomes	Results	Quality score
Minocycline	Weiser M, Levi L, Burshtein S, et al. [27]	Efficacy of minocycline over positive, negative and cognitive symptoms of schizophrenia	16-week double-blind, placebo-controlled RCT; minocycline (200 mg/day) /pramipexole /acetyl- salicilic acid/ placebo as add-on to antipsychotic treatment	N=200 patients with schizophrenia or schizo-affective disorder	Primary outcome measurements - PANSS total score at the end of the trial. Secondary outcomes- positive, negative and general psychopathology scored by PANSS; CGI-S, CGI-I; BACS; rates of drop-outs	No significant differences between minocycline and placebo for PANSS total score, PANSS subscales, CGI, and BACS were detected. No significant difference between groups in the frequency of adverse events.	High
Minocycline	Deakin B, Suckling J, Barnes TRE, et al. [28]	Efficacy of minocycline over negative symptoms in schizophrenia with recent onset	12-month double-blind, placebo-controlled RCT; minocycline (200 mg/day for 2 weeks, then 300 mg/day for the remainder of 12 months) vs. placebo plus continuing treatment	N=207 patients with schizophrenia spectrum disorders that begun in the last 5 years	Negative symptom subscale score of the PANSS; prefrontal grey matter volume, dorsolateral prefrontal cortex activation during working memory task, and plasma concentration of IL6	No effect of minocycline was observed over ratings of negative symptoms. Biomarker outcomes did not change over time, and were not affected by minocycline. No difference in the appearence of serious adverse events was detected between groups.	High
Minocycline	Liu F, Xie L, Zhang B, et al. [30]	Effects of adjunctive minocycline over body metabolism in risperidone- treated patients with schizophrenia	16-week placebo-controlled, double-blind crossover RCT	N=63 patients diagnosed with schizophrenia,treated with stable dose of risperidone for ≥4 weeks	Body weight, BMI, waist circumference, fasting insulin, glucose and lipids serum levels	No difference between groups was detected ($P's>0.3$)	Moderate
Minocycline	Wehring HJ, Elsobky T, McEvoy JP, et al. [29]	Pharmacokinetic impact of minocycline over clozapine and correlation between modified levels of clozapine /norclozapine over negative symptoms in schizophrenia	10-week placebo-controlled RCT, minocycline vs. placebo as add-on to clozapine	N=73, DSM IV-TR-based diagnoses of schizophenia or schizo-affective disorder, currently treated with clozapine ≥200 mg/day and blood level of clozapine ≥350 ng/ml.	Serial plasma clozapine, norclozapine and total clozapine levels, SANS	Clozapine plasma levels are increased after the initiation of minocycline (21% increment to baseline) compared to placebo. However, smoking patterns were not analysed in relation to this plasmatic difference in concentration. Avolition improvement on SANS was not explained by changes in clozapine blood levels. There is no evidence that improvement in any symptom domain is due to higher clozapine levels.	Moderate
Minocycline	Kelly DL, Sullivan KM, McEvoy JP, et al. [31]	Efficacy of minocycline as adjunctive treatment to clozapine in chronic psychoses	10-week double-blind, placebo-controlled RCT; 100 mg p.o BID minocycline vs. placebo.	N=52 patients with schizophrenia and schizo-affective disorder with persistent positive symptoms	Positive and cognitive symptoms were primary outcomes. Avolition, anxiety/depression, and negative symptoms were secondary outcomes.	BPRS- psychosis factor and BPRS- total score were not changed significantly during treatment. Still, a change in total BPRS score of more than or equal to 30% was observed more frequently in minocycline treated patients (p=0.044). Global cognitive function (MATRICS) did not differ between groups, but significant	Moderate

Intervention	Authors	Objectives	Design	Population	Outcomes	Results	Quality score
						improvement in working memory favored minocycline. SANS total score did not differ, but minocycline improved significantly working memory (p=0.023). Significant improvement in the BPRS anxiety/depression factor was observed with minocycline (p=0.028). The overall tolerability of minocycline was good.	
Minocycline	Chaves C, Marque CR, Maia-de-Oliveira JP, et al. [32]	Effects of minocycline on brain morphology and cerebral perfusion in patients with recent-onset schizophrenia	12-month double-blind, placebo-controlled RCT of minocycline as add-on treatment (200 mg/day minocycline vs. placebo)	N=24 outpatients with recent-onset schizophrenia	SPECT and MRI were performed after 12 months of treatment for detection of morphologic changes.	Minocycline may have protective effect against gray matter loss and modulate fronto-temporal areas involved in the pathophysiology of schizophrenia. Significant lower gray matter volumes were observed in the midposterior cingulate cortex and in the precentral gyrus in placebo group, in comparison with minocycline group. Positive and negative symptoms were significantly decreased versus placebo.	Moderate
Minocycline	Ghanizadeh A, Dehbozorgi S, Omrani Sigaroodi M, Rezaei Z [33]	Effectiveness of add-on minocycline in schizophrenia	8-week placebo-controlled RCT; minocycline 200 mg/day + risperidone vs. placebo + risperidone.	N=43 patients diagnosed with DSM IV schizophrenia	Schizophrenia negative symptoms severity as primary outcome	SANS total score decreased significantly in the minocycline group at week 8, compared with placebo group. The decline of PANSS Negative score was more in the active treatment group than in the placebo group (not statistically signifi-cant). Tolerability of minocycline was good.	Moderate
Minocycline	Liu F, Guo X, Wu R, et al. [34]	Efficacy and safety of minocycline for the treatment of negative symptoms and cognitive impairments in patients with schizophrenia	16-week double blind, placebo-controlled RCT; minocycline 200 mg/day vs. placebo.	N=92 with early stage schizophrenia treated with risperidone	The primary outcome was represented by negative symptoms of schizophrenia, evaluated by SANS scores. Secondary outcomes were scores of response rate on SANS, PANSS, CGI, cognitive tests	Patients receiving minocycline had greater improvements on SANS total scores and PANSS negative subscale scores vs. placebo. Rates of treatment response in the minocycline group were significantly higher than those in the placebo group after 16 weeks of treatment. Cognitive performances were not improved significantly by minocycline, except for the attentional domain.	High
Minocycline	Khodaie-Ardakani MR, Mirshafiee O, Farokhnia M, et al. [35]	Efficacy and tolerability of minocycline add-on to risperidone in treatment of negative	8-week double-blind, placebo-controlled RCT; minocycline (titrated up to 200 mg/day) vs. placebo as add-on to	N=40 outpatients with chronic schizophrenia stabilized on risperidone for at least 8 weeks prior to baseline	Primary outcomes- negative symptoms evaluated by PANSS	Significant difference between groups on negative scale of PANSS favoured minocycline at the end of the trial (p<0.001). PANSS total score, positive score and general psychopathology score were also improved by minocycline compared to placebo.	Moderate

Intervention	Authors	Objectives	Design	Population	Outcomes	Results	Quality score
		symptoms in chronic schizophrenia	risperidone (maximum 6 mg/day)			No difference between groups regarding the severity of adverse effects was observed.	
Minocycline	Chaundhry IB, Hallak J, Husain N, et al. [36]	Efficacy of minocycline as add-on to treatment as usual over negative symptoms in early psychosis.	Placebo-controlled RCT, one year duration, minocycline (titrated up to 200 mg/day) vs. placebo.	N=144 patients with early psychosis	Primary outcomes- negative and positive symptoms evaluated by PANSS. Secondary outcomes- GAF, CGI, AIMS, neuropsychological outcome measures.	Minocycline improved negative symptoms (p<0.001) in the ITT population. No other outcomes were influenced significantly by minocycline. AIMS scores tend to improve more in the placebo group.	High
Minocycline	Levkovitz Y, Mendlovich S, Riwkes S, et al. [37]	Efficacy of minocycline as add-on treatment for alleviating negative and cognitive symptoms in early-phase schizophrenia	Double-blind, placebo-controlled RCT, 6 months duration, minocycline 200 mg/day vs. placebo + atypical antipsychotic (200-600 mg/day chlorpromazine-equivalent doses).	N=54 early-phase schizophrenia patients (DSM IV) - age 18-35 years	Primary outcome- negative symptoms severity evaluated by SANS. Cognitive measures evaluated by CANTAB. Functional measures and clinical evaluations by GAF, SOFAS, MCAS, CGI.	A significant time effect for SANS total scores was detected in the minocycline group, negative symptoms improved since week 14. CGI improved better with minocycline, as did cognitive functioning, mainly executive functions (working memory, cognitive shifting, and cognitive planning). GAF and SOFAS showed a better improvement with minocycline. Also, minocycline had a favourable effect in preventing weight gain during treatment.	Moderate
Minocycline	Miyaoka T, Yasukawa R, Yasuda H, et al. [38]	Efficacy and tolerability of minocycline as adjunct to antipsychotic medication in schizophrenia	Open-label, pilot study, minocycline 150 mg/day 4 weeks as adjunct to current antipsychotic medication	N=22 patients with schizophrenia	Psychotic symptoms severity determined by PANSS	All scales of PANSS improved during minocycline treatment. All patients tolerated the full dose during the study.	Low
D-cycloserine	Takiguchi K, Uezato A, Itasaka M, et al. [39]	Effects of d-cycloserine over positive, negative and cognitive symptoms of schizophrenia. To investigate if white matter integrity influences response to d-cycloserine.	6-week placebo-controlled, double-blind, cross-over design RCT; d-cycloserine (50 mg) vs. placebo as add-on to their current antipsychotic treatment	N=41 patients, in- and out- patients with DSM IV diagnostic criteria for schizophrenia	PANSS and SANS scores, BACS, EQS- interpersonal, intrapersonal and situational domains; correlations between d-cycloserine treatment and MR-DTI white matter integrity.	No improvement of positive, negative, or cognitive symptoms of schizophrenia. The better treatment effect of d-cycloserine on BACS was observed when fractional anisotropy was higher in sagittal striatum, cingulum, fornix stria terminalis, genu of corpus callosum, and external capsule, and the better treatment effect on PANSS- general psychopathology score was observed when fractional anisotropy of the splenium of corpus callosum was higher. The better treatment effect on PANSS- general psychopathology score and SANS-IV was observed when fractional anisotropy was lower in the posterior thalamic radiation.	Moderate

Intervention	Authors	Objectives	Design	Population	Outcomes	Results	Quality score
D-cycloserine	Forsyth JK, Bachman P, Mathalon DH, et al. [40]	Exploration of NMDA-receptor signaling on working memory and experience-dependent plasticity	Double-blind, placebo-controlled, between-group design RCT, 100 mg d-cycloserine vs. placebo; subjects were tested at one day after d-cycloserine or placebo administration	N=45 patients diagnosed with schizophrenia	Neuroplasticity changes evaluated by cognitive tests and EEG with high-frequency visual stimulation	D-cycloserine did not affect plasticity (similar neural potentiation in both active and placebo group), similar information integration and weather prediction tasks performances. Still, patients who received active drug and who were actively involved in memory task had superior 2-back performace compared to placebo-receiving patients. NMDA-receptor-signaling was not translated into synaptic plasticity change in schizophrenia.	Moderate
D-cycloserine	Cain CK, McCue M, Bello I, et al. [41]	Efficacy of d-cycloserine + cognitive remediation (CR) program in improving memory of patients with schizophrenia	8-week placebo-controlled RCT; 3-5 times per week CR program + once-weekly adjunctive treatment with 50 mg d-cycloserine or placebo administered before the first session within each week.	N=36 outpatients, stable medicated adults	Primary outcomes were performances on an auditory discrimination task, MATRICS battery composite scores, SANS total scores	Performance on the practiced auditory discrimination task significantly improved in the d-cycloserine group compared to placebo. Active treatment was associated with significantly greater negative symptom improvement for subjects symptomatic at baseline. Improvement on MATRICS was observed only in the placebo group.	Moderate
D-cycloserine	Gottlieb JD, Cather C, Shanahan M, et al. [42]	Efficacy of d-cycloserine as add-on to CBT for the management of delusions in schizophrenia	Double-blind, cross-over, placebo controlled RCT, single oral dose of d-cycloserine 50 mg vs. placebo, one hour post-drug administration patients received 2 CBT sessions focused on challenging patients' paranoid appraisals, with 7-day and 14-day re-evaluations	N=21 outpatients diagnosed with schizophrenia or schizo-affective disorder and moderately severe delusions	Delusional severity was assessed using SAPS; alternative explanations generated on the ABA; PSYRATS score	No significant effect of d-cycloserine on delusional distress or severity has been reported.	Moderate
D-cycloserine	Goff DC, Cather C, Gottlieb JD, et al. [43]	Investigation of d-cycloserine over negative symptoms and cognition in schizophrenia	8-week double-blind, parallel-group RCT; add-on of d-cycloserine 50 mg or placebo administered once-weekly.	N=50 adult outpatients treated with any antipsychotic except clozapine	Primary outcomes were change from baseline to week 8 on SANS total score and on a composite cognitive score.	D-cycloserine significantly improved SANS total scores compared to placebo at week 8. Cognitive performance did not improve with d-cycloserine at week 8. Delayed thematic recall was significantly improved with the first dose of d-cycloserine vs. placebo, but not immediate thematic recall and item recall.	High

Intervention	Authors	Objectives	Design	Population	Outcomes	Results	Quality score
D-cycloserine	Buchanan RW, Javitt DC, Marder SR, et al. [44]	Efficacy of glycine or d-cycloserine in patients with schizophrenia with moderate to severe negative symptoms and cognitive impairments.	16-week double-blind, double-dummy, parallel-group RCT of adjunctive glycine, D-cycloserine, or placebo	N=157 inpatients and outpatients diagnosed with DSM-IV schizophrenia or schizo-affective disorder and retrospective and prospective criteria for moderate to severe negative symptoms without marked positive, depressive, or extra-pyramidal symptoms	The primary outcome- average rate of change of SANS total scores and change in the average cognitive domain z scores	No significant differences in change of the SANS total score between glycine and placebo, or d-cycloserine and placebo. No significant differences between glycine and placebo or d-cycloserine and placebo were recorded on the average cognition z score.	High
D-cycloserine	Yurgelun-Todd DA, Coyle JT, Gruber SA, et al. [45]	Examination of patterns of cortical activation underlying d-cycloserine's therapeutic efficacy in patients with schizophrenia	2-week single-blinded, placebo lead-in phase RCT; after placebo phase, patients received 50 mg/day d-cycloserine or placebo in a double-blind manner for 8 weeks.	N=12 out- and in-patients with DSM-IV criteria for schizophrenia on stable dose of antipsychotic for at least 4 months and presenting prominent negative symptoms	fMRI patterns of cortical activation; SANS for severity of negative symptoms	Patients receiving d-cycloserine had a significant increase in temporal lobe activation, associated with reduction in negative symptoms.	Low
D-cycloserine	Goff DC, Herz L, Posever T, et al. [46]	Efficacy of d-cycloserine as augmenting agent for conventional antipsychotics in decreasing negative and cognitive symptoms of schizophrenia	Double-blind, parallel-blind RCT, 50 mg/day d-cycloserine or placebo for 6 months	N=55 patients with schizophrenia with prominent negative symptoms	Primary outcomes- negative symptoms and cognitive impairments evaluated by PANSS, SANS, cognitive battery	No difference between groups was detected on any primary outcome at 8 or 24 weeks (PANSS, SANS, cognitive tests).	High
D-cycloserine	Duncan EJ, Szilagyi S, Schwartz MP, et al. [47]	Efficacy of d-cycloserine over negative and cognitive symptoms of schizophrenia	Double-blind, parallel-group RCT, 50 mg QD d-cycloserine or placebo for 4 weeks	N=22 male patients with schizophrenia displaying prominent negative symptoms stabilized on typical neuroleptics	Symptoms severity (SANS, BPRS, Abrams and Taylor rating scale). Cognition was assessed by the Sternberg Memory Test and the Continuous Performance Test.	No significant differences between the d-cycloserine and placebo group on any symptom rating	Low
D-cycloserine	Evins AE, Amico E, Posever TA, et al. [48]	Effects of d-cycloserine when added to risperidone	Placebo-controlled RCT, 2 weeks of placebo and 4 doses of d-cycloserine	N=10 patients with schizophrenia treated with risperidone	Negative symptoms severity	D-cycloserine (50 mg/day) significantly reduced negative symptoms.	Low

Intervention	Authors	Objectives	Design	Population	Outcomes	Results	Quality score
		on negative symptoms of schizophrenia				Ratings of depression, extrapyramidal side effects, and cognitive function were unchanged.	
D-cycloserine	Heresco-Levy U, Ermilov M, Shimoni J, et al. [49]	To investigate the clinical effects of d-cycloserine when added to conventional antipsychotics, olanzapine, or risperidone for treatment-resistant schizophrenia	Double-blind, placebo-controlled, crossover study, 2 random-order 6-week treatment arms (d-cycloserine, 50 mg/day vs. placebo), separated by 2-week adjuvant treatment washout.	N=24 patients diagnosed with treatment-resistant schizophrenia, and they were on stable doses of medication for at least 3 months before study entry	Psychotic symptoms evaluated by PANSS, depression severity evaluated by HAMD, and adverse events quantified by SAS and AIMS	Significant reduction in negative symptoms in patients treated with d-cycloserine. No difference between patients treated with conventional neuroleptics or atypical antipsychotics was observed.	Moderate
D-cycloserine	Heresco-Levy U, Javitt DC, Ermilov M, et al. [50]	Efficacy of d-cycloserine over negative symptoms in schizophrenia	16-week, double-blind, placebo-controlled, adjuvant treatment RCT with 50 mg/day d-cycloserine	N=9 treatment-resistant chronic schizophrenia-diagnosed patients	Psychotic symptoms evaluated by PANSS, depression severity evaluated by HAMD, and adverse events quantified by SAS and SAS and AIMS	Symptoms changes between groups were not significant, except for a significant reduction in negative symptoms which was registered during treatment with d-cycloserine but not placebo. Greater reductions were registered in patients with lower baseline serum glycine levels. No side effects were registered.	Low
D-cycloserine	van Berckel BN, Evenblij CN, van Loon BJ, et al. [51]	Effects of d-cycloserine as add-on to typical antipsychotics in reducing negative symptoms in schizophrenia	Double-blind, parallel group, placebo-controlled RCT; 50 mg d-cycloserine BID or placebo for 8 weeks.	N=26 patients with DSM-IV schizophrenia	PANSS, CGI, ESRS	D-cycloserine slightly worsened positive symptoms and general psychopathology compared to placebo. No significant change in negative symptoms was detected or extrapyramidal symptoms. Tolerability of d-cycloserine was good.	Moderate
D-cycloserine	Goff DC, Henderson DC, Evins AE, Amico E [52]	Effects of d-cycloserine over negative symptoms in schizophrenia	6-week RCT, d-cycloserine 50 mg/day or placebo, crossover design separated by 1 week placebo washout for a total of 13 weeks	N=17 outpatients diagnosed with schizophrenia (DSM-IV criteria) treated with clozapine	PANSS, SANS, GAF, HAMD, AIMS, SAS, BAS	D-cycloserine significantly worsened negative symptoms compared to placebo (increased SANS scores and negative subscale of PANSS)	Moderate
D-cycloserine	Goff DC, Tsai G, Levitt J, et al. [53]	Efficacy of d-cycloserine over negative symptoms and cognitive function when added to conventional neuroleptics	8-week double-blind RCT, d-cycloserine 50 mg/day vs. placebo, added to their conventional neuroleptic	N=47 patients with schizophrenia meeting criteria for deficit syndrome	SANS total score	The mean reduction in negative symptoms with d-cycloserine was significantly greater than with placebo (SANS scores). No differences were found in performance on any cognitive test between groups or in changes in any other clinical measure.	Moderate

Intervention	Authors	Objectives	Design	Population	Outcomes	Results	Quality score
D-cycloserine	Goff DC, Tsai G, Manoach DS, et al. [54]	Efficacy of d-cycloserine as add-on over negative symptoms in patients treated with clozapine	2-week placebo-controlled RCT; 5, 15, 20, 50 and 250 mg/day d-cycloserine	N=10 outpatients with schizophrenia receiving clozapine who presented criteria for primary deficit syndrome	SANS	Significant dose effect of d-cycloserine on SANS scores, 50 mg/day produced a mean increase of 21% in SANS score. No improvement was detected on clozapine-treated patients with negative symptoms.	Low
D-cycloserine	Rosse RB, Fay-McCarthy M, Kendrick K, et al. [55]	Efficacy of d-cycloserine as add-on to molindone in schizophrenia	4-week placebo-controlled, double-blind, parallel-group RCT, 10 or 30 mg/day d-cycloserine as adjuvant to molindone (150 mg QD)	N=13 patients diagnosed with schizophrenia	BPRS, SANS, CGI	Neither dose of d-cycloserine had adjuvant therapeutic efficacy, although the tolerability of the d-cycloserine was good.	Low
D-cycloserine	Goff DC, Tsai G, Manoach DS, Coyle JT [56]	Efficacy of d-cycloserine over negative symptoms of schizophrenia	2-week trials of placebo and four doses of d-cycloserine; 5, 15, 50, 250 mg/day d-cycloserine	N=9 outpatients with schizophrenia (DSM III R criteria) treated with stable doses of conventional antipsychotics for at least 4 months prior to inclusion	SANS, Negative symptoms subscale of BPRS, SAS, AIMS, GAF, Sternberg's Item Recognition Paradigm	D-cycloserine at 50 mg/day produced significant reduction in negative symptoms and significantly improved reaction time (as a measure of executive dysfunction)	Low

RCT = randomized controlled trial; MR-DTI = Magnetic resonance - diffusion tensor imaging; PANSS = Positive and Negative Syndrome Scale; SANS = Scale for the Assessment of Negative Symptoms; EQS = Emotional Intelligence Scale; BMI = Body Mass Index; BPRS = Brief Psychiatric Rating Scale; ITT = Intent to treat analysis; GAF = Global Assessment of Functionality Scale; CBT = Cognitive Behavioral Therapy; SAPS = Scale for the Assessment of Positive Symptoms; ABA = Alternative Beliefs Assessment; PSYRATS = Psychotic Symptom Rating Scale; CANTAB = Cambridge Neuropsychological Test Automated Battery; SOFAS = Social and Occupational Functioning Assessment Scale; MCAS = Multinomah Community Ability Scale; HAMD = Hamilton Depression Rating Scale; SAS = Simpson-Angus Rating Scale; AIMS = Abnormal Involuntary Movement Scale; ESRS = Extrapyramidal Symptoms Rating Scale; BAS = Barnes Akathisia Scale; CGI-S = Clinical Global Impressions- Severity; CGI-I = Clinical Global Impressions- Improvements; BACS = Brief Assessment of Cognition in Schizophrenia

Another 8-week trial (n=40) confirmed significant differences between groups in favour of minocycline regarding the negative symptoms evaluated by PANSS, while positive and general psychopathology scores were non-significantly improved [35].

A large, long-term trial (n=144, 12 months) reported that minocycline improved negative symptoms in the ITT population (p<0.001) [36]. The efficacy of minocycline over negative symptoms was supported also by a study (n=54) which included early-phase schizophrenia patients, with difference between groups appearing at week 14 [37]. An open-label study confirmed a positive effect of minocycline over all scales of PANSS after 4 weeks [38].

D-cycloserine was associated with lack of efficacy over positive, negative and cognitive psychotic symptoms, in a small trial (n=41), but some interesting correlations were reported between MR-DTI (Magnetic resonance - diffusion tensor imaging) and score evolution of general and cognitive symptoms, i.e. fractional anisotropy in certain thalamic regions (where assymetric alterations in the white matter integrity were demonstrated) could be improved by this antibiotic and it may be a mediator of the therapeutic response [39].

No significant effects were observed in patients treated with d-cycloserine over neuroplasticity and cognitive performances, evaluated by cognitive tests and EEG with high-frequency visual stimulation, in a small trial (n=45) [40]. In a crossover design study, no significant effect of d-cycloserine on delusional distress or severity has been reported [42].

Data from a large trial (n=157) found no difference between d-cycloserine and placebo over the severity of cognitive and negative symptoms [44]. No significant differences were found between d-cycloserine and placebo in two trials, which included patients with prominent negative symptoms in the domains of negative and cognitive manifestations [46, 47]. D-cycloserine slightly worsened positive symptoms and general psychopathology compared to placebo, and it did not significantly change negative symptoms in an 8-week placebo-controlled trial (n=26) [51]. D-cycloserine significantly worsened negative symptoms compared to placebo in a 13-week trial (n=17) [52]. When added to clozapine, d-cycloserine worsened negative symptoms dose-proportionally in a small study (n=10) [54]. D-cycloserine added to molindone did not resulted in improvements of general psychopathology or negative symptoms (n=13) [55].

Regarding the positive results of d-cycloserine, this drug was significantly superior to placebo on reducing negative symptoms compared to placebo (n=36, 8-week trial) [41]. D-cycloserine significantly improved SANS total scores after 8 weeks in small trial with outpatients, but no effect was observed over cognitive functions (n=50) [43]. A small trial (n=12) found that d-cycloserine increased significantly temporal lobe activation, a phenomenon correlated with negative symptoms [45].

Table 4: Efficacy of antibiotics over symptom severity in schizophrenia spectrum disorder

Treatment	Clinical trials	GRADE Recommendations
Minocycline	[27-29,31-38]	Positive symptoms: ? Negative symptoms: D+ Cognitive symptoms: D+ Behavioral symptoms: ? Affective symptoms: D Overall symptoms: D+
D-cycloserine	[39-45,48,50-56]	Positive symptoms: ? Negative symptoms: D+ (but not as add-on to clozapine) Cognitive symptoms: ? Behavioral symptoms: ? Affective symptoms: ? Overall symptoms:?

GRADE recommendations for the level of evidence [57]: A=high quality= future research are very unlikely to change the validity of these recommendations; B= moderate quality= future research is likely to have an important impact on the appreciation of the recommendations; C=low quality= it is very likely that future research will have an important impact over the confidence in the estimate of effect and is likely to change the recommendations; D= very low quality= any estimate of the effect is very uncertain. Intermediate steps (+ or -) represent nuances of the recommedantions based on the quality of trials and tolerability of antidepressant agents, as resulted from these trials.

Another small trial (n=10) signaled reduced negative symptoms with d-cycloserine, but no effect of the same drug over cognitive function [48]. In a trial with treatment-resistant schizophrenia-diagnosed patients, adding d-cycloserine to current antipsychotic agent has lead to significant reduction in negative symptoms, without differences between patients treated with atypical or typical antipsychotics [49].

A small trial (n=9) reported significant improvements in negative symptoms versus placebo, especially in patients with lower baseline serum glycine levels [50]. A significant reduction in negative scores (evaluated by SANS) was observed in an 8-week double blind RCT (n=47), but no effect was detected over cognitive symptoms [53]. When added to conventional antipsychotics, D-cycloserine 50 mg/day produced significant reduction in negative symptoms and improved executive dysfunction in patients with schizophrenia (n=9) [56].

3.3. Evaluation of antibiotics tolerability in the studied population

Tolerability of minocycline was evaluated in a number of nine trials of moderate quality, most of them being double blind, placebo-controlled, that included 825 patients, and had variable duration (between 4 weeks and 12 months). Most of these trials included small groups, but there were also 3 large-group (over 140 patients each) studies [27, 28, 36].

No significant differences in the rate of adverse events between minocycline- and placebo-treated patients were reported [27, 28, 31, 32, 35, 36, 38].

No difference between minocycline and placebo was detected in a study focused on tolerability in the domain of body weight, waist circumference, fasting insulin, glucose and lipid serum levels [30]. Minocycline had a favourable effect in preventing weight gain during treatment in a trial with early-phase schizophrenia patients (n=54) [37].

Tolerability of d-cycloserine was evaluated systematically in 6 trials, of low-to-moderate quality, that included 99 patients, with a duration between 2 and 16 weeks [44, 48-51, 55]. All these trials reported a good tolerability of d-cycloserine, and the main adverse events monitored were extrapyramidal symptoms. However, none of the trials, which included scales for extrapyramidal symptoms, reported any significant changes during d-cycloserine administration [49-52, 56].

3.4. Evaluation of general functionality and global clinical status

Minocycline improved the global clinical impression in only one study (n=54) [37], while in other three studies (with a total of 436 subjects) it did not distinguished itself from placebo [27, 34, 36]. Trials included in this analysis were of high quality.

The global functioning was improved by minocycline more than by placebo in one trial (n=54) [37], but did not differ from placebo in another trial (n=144) [36]. The quality of these trials was high to moderate.

D-cycloserine had no significant impact over global clinical status or overall functionality, but data were derived from only 2 trials for each outcome, and they included low number of participants (39 and 26, respectively) and were of moderate to low quality [51, 52, 55, 56].

CONCLUSIONS

Based on reviewing the selected trials regarding the efficacy of antibiotics as add-on to antipsychotic treatment over core symptoms of schizophrenia, minocycline (n=10 trials, N=950 participants) was associated with mixed results regarding its efficacy, both positive [32-38] and negative [27-29, 31]. The large majority of these studies were of moderate and low quality, which further complicates the evaluation of their conclusions. Most of the data derived from these trials did not support a significant efficacy of minocycline over negative, cognitive, and overall psychotic symptoms, when it was added to various antipsychotic agents, clozapine included [27-29]. Other trials reported isolated efficacy of minocycline superior to placebo over anxiety/depression factor of BPRS, working memory, or significant improvement in negative and/or positive symptoms [31-38]. Non-significant superior efficacy of minocycline over placebo was also reported over positive and general psychopathology [35]. A definite conclusion about the efficacy of minocycline can not be formulated based on these data, and the GRADE recommendation could not be over the D+ level regarding the positive, negative, and overall psychotic symptoms, as well as D level for affective symptoms of schizophrenia (table 4).

D-cycloserine was investigated in moderate quality trials (n=18, N=626 participants) focused on its efficacy over symptoms of schizophrenia, when used as add-on to antipsychotics. No significant difference between d-cycloserine and placebo was observed in trials focused on negative and cognitive symptoms of schizophrenia [39-56]. A trend to the worsening of positive symptoms by d-cycloserine was also reported, as well as a trend to aggravation of negative symptoms, especially when added to clozapine [51, 52, 54]. D-cycloserine was also proven superior to placebo over negative symptoms [41, 43, 45, 48-50, 53, 56] and cognitive function [56], without difference between atypical and typical antipsychotics as main treatment [49]. Based on these contradictory data, d-cycloserine could be rated as D+ recommendation for the treatment of negative symptoms of schizophrenia, when added to typical or atypical antipsychotics, but not to clozapine. Thorough monitorisation of patients undergoing d-cycloserine augmentation should be initiated because there is a risk of worsening positive symptoms or negative symptoms (the last case has been reported in clozapine-treated patients).

After reviewing the trials focused on tolerability of antibiotics in patients diagnosed with schizophrenia as add-on to antipsychotics (n=9, N=825 participants), the data collected was considered as being of moderate quality (table 5). Almost all of them reported no difference in the rate of adverse events between minocycline and placebo-treated patients, and two studies showed a favorable effect of this antibiotic over metabolic status of the patients undergoing antipsychotic treatment [27, 28, 30-32, 35-38]. These data support a level B- for the tolerability of minocycline as add-on to antipsychotic regarding the metabolic profile, body weight and waist circumference, and level B for the overall adverse events (extrapyramidal symptoms included).

Tolerability of d-cycloserine was also evaluated as good in moderate to low quality trials (n=6 studies, N=99 participants), and the main adverse events were extrapyramidal symptoms [44, 48-51, 55]. These data support a level B- for the tolerability of d-cycloserine as add-on to antipsychotic regarding the overall adverse events (extrapyramidal symptoms included).

Minocycline had an effect over the clinical global impression that was not disguinshible from placebo [27, 34, 36], although there was one exception [37]. Data was derived from high quality studies (n=4, N=490 participants), and the recommendation for improving this outcome with minocycline as add-on is D- (table 6). The impact of minocycline over the global functioning when added to antipsychotic in patients with schizophrenia was mixed, with one positive and one negative trial (n=2, N=198 participants, moderate to high quality designed trials) [36, 37]. Based on these data a D level is formulated in this case.

D-cycloserine had no significant impact over global clinical status (n=2, N=39 participants) or overall functionality (n=2, N=26 participants) [51, 52, 55, 56]. These trials were of moderate to low quality and there was formulated a D- recommendation for each outcome based on the before-mentioned results (Tables 6 and 7).

From all the data reviewed and hierarchized it is evident that larger trials are needed in order to confirm the efficacy of minocycline and d-cycloserine over negative and cognitive symptoms of schizophrenia. The tolerability of these two antibiotics was good in almost all trials that were reviewed, which is encouraging in the perspective of designing new trials with these agents.

Limitations of this review are related to the heterogeneity of design in trials that were analysed, and the impossibility of contructing a meta-analysis. The use of different scales for monitoring the same cluster of symptoms made difficult the comparison of the results. In addition, most of the trials included in the current review were conduceted on small groups, which make the generalizability of data very difficult.

Ego-strength mediates the relationship between religious health behaviors and mental health symptoms during the COVID-19 pandemic in Iran

Seyedeh A. Hosseini[1]

Abstract: *The present study aimed to examine the mediating role of ego-strength in the relationship between religious health behaviors and mental health symptoms during the COVID-19 pandemic in Iran. A total of 346 university students (301 women, 45 men) completed the Ego-Strength Scale, Religious Health Promoting Behaviors Inventory, and Mental Health Inventory from May 2021 to August 2021. The structural equation modeling and the Pearson correlation method were used. The results revealed that religious health behaviors have a positive and significant relationship with, psychological well-being, and ego-strength, as well as a negative significant relationship with psychological distress. The results also showed ego-strength has a negative relationship with psychological distress. Ego-strength mediated the relationship between religious health behaviors and symptoms of mental health. Ego-strength can be considered as a very important variable in religious health psychology; reinforcing ego-strength may have some implications for mental health during the Covid-19 pandemic.*

Keywords: *ego-strength, health behavior, religious health behavior, mental health, Covid-19*

INTRODUCTION

COVID-19 pandemic is the widest public health crisis in the world. In addition to the huge physical health threat of the COVID-19 pandemic, long feelings of uncertainty and fear, grief and separation, upset of economic and social systems have led to mental health threats [1]. The impacts of COVID-19 on mental health are alarming [2]. As Erikson (1965) suggested, ego-strength may be defined as specified qualities that start to animate the individuals comprehensively within successive periods of life [3]. Ego-strength is related to self-regulation. The term self-regulation is generally understood to mean a process that is guided by goals and its aims to achieve and sustain one's goals [4]. When a person has mental health, there is a consonance between id, ego, and superego [5]. The ego-strength also is one of the personality characteristics, and is defined as the attitude of a person toward his problems, his general response to distress, and his adaptive ability in situations which are emotional [6]. In other words, ego-strength is the extent of power that the ego works in adjusting the impulses and adapting to the environment. The balance while postponing the gratification of needs can be prepared by ego-strength. When the ego-strength is low, people experience a lack of motivation and confidence and believing that they are incompetent. But elevated ego-strength helps the persons to be resilient, motivated, confident, and trusting themselves and their capabilities; thus, they are likely to adapt to challenges [7].

In a study that used group psychotherapy that included components of individual psychotherapy, the majority of participants showed an increase in their ego-strength [8]. Another study among students showed that some variables such as sports, student government, and volunteerism were associated with ego-strength. Also, religious attendance wasn't related to ego-strength [9]. In another study, authoritative parenting and extroversion were related to ego-strength. Also, extroversion has moderated the association between authoritative parenting and ego-strength [10]. In one study, aggressive alcoholics had weaker ego-strength than non-aggressive alcoholics [11]. One of the

S.A.Hosseini@Alzahra.ac.ir

variables of the present study is ego-strength which despite its great importance, has received little attention in psychological research. As a result, addressing it can open up new horizons for the science of psychology.

Also, some studies have shown the important role of ego-strength in mental health [10]. Mental health is one of the most important psychological variables. increasingly, the rates of mental disorders in colleges across the world are rising [12]. One of the major researches carried out by WHO in 21 countries indicated that one-fifth (20.3%) of college students had 12-month DSM-IV/ICD-10 disorders [13]. Many research suggesting that religious/spiritual behaviors and beliefs are correlated with mental health [14]. A systematic review indicated that religious involvement is associated with higher mental health especially in the domain of substance abuse, depression, and suicide [15]. Mental health is also considered in the present study. In particular, mental health is very important for university students and according to the statistics mentioned above, it is very important to address it. As a result, the present study deals with the mental health variable in students.

One recent study found a correlation between religiousness and a lower probability of depressive symptoms, especially in individuals that attending religious service [16]. Lots of people benefit from religious beliefs and practices to cope with stressful life happenings and enjoy mental peace and purpose in life. A comprehensive systematic review has shown that there is an association between religion, psychiatry, psychology, and medical care [17]. The correlation between religiousness and health can be largely explained by lifestyle [18]. A healthy lifestyle is very essential for a good life. Adequate physical activity and a limited amount of passive behavior can prevent various chronic diseases [19]. To date, many studies suggest the relationship between religious involvement and a variety of health outcomes. Some of them hypothesize the influence of religion on "health behaviors". But the underlying processes of the connection of religion and health have been studied very little [20].

Religion is the most momentous component of human nature for attaining the meaning and purpose of life. It has a great role in the patient's health [21]. Religion is a serious protective effect on risky health behaviors [22]. Greater religious involvement is correlated with positive lifestyle practices [23]. A study indicated that there is a relationship between risky drinking and religion. The religious group in contrast to the non-religious group had a lower probability of risky drinking [24].

Some studies indicated that self-efficacy and self-esteem are mediators of the relationship between religious involvement and health outcomes. But there is mixed evidence about the relationship. For example, one of the studies indicated that self-esteem and self-efficacy mediated, at least in part, the relationship between religious beliefs and better vegetable and fruit consumption, and lower alcohol consumption. Also, religious behaviors have a direct impact on health behaviors [25]. Research outcomes suggested that self-regulation can be the expository mechanism for the association between religiosity and positive health behaviors. However, various religious motivations have different impacts on health-related outcomes. These can be the reason for the negative effects of religion that are found in some research. One study suggested that self-regulation mediated the association between religious motivation and health behaviors [26].

A study indicated that a religious intervention can improve the patient's health [27]. Another study suggested that an intervention based on religion can promote the health of patients. In several studies, religious interventions had a desirable impact on patients [28]. Health behavior components also can predict mental health levels [29]. Psychological health is related to physical health outcomes. One of the effective components of this relationship is health behaviors. Higher distress is related to less eating fruits and vegetables and physical activity, and higher sedentary behaviors and smoking [30]. Also, mental illness and health behaviors are associated strongly. But the causality of the link is challenging. A new study indicated the correlation between psychological distress and health behaviors. Furthermore, there is a causal relationship between psychological distress and health behaviors [31].

The underlying processes of the connection between religion and health have been studied very little [20]. Also, interest in the role of religion and spirituality in mental health is increasing [17]. Due to the remarkable burden of disease which is correlated to unhealthy behaviors, more research is needed to understand the causal links between mental health and health behaviors [31]. Given the ascendant rates of mental disorders in colleges across the world [12], the correlation between religious/spiritual behaviors and beliefs with mental health [14], the importance of research in this field, the relatively high levels of religious involvement among some cultures, and the important role that ego-strength may play in the relationship of religious health behaviors and mental health and illness, the present study examined the mediating role of ego-strength in the relationship between religious health behaviors and mental health symptoms and illness in a group of university students.

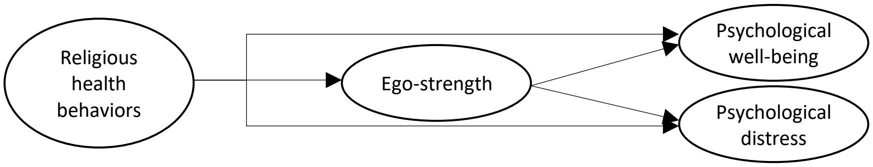
The research hypotheses in the present study are as follows: (1) there is a positive significant relationship between religious health behaviors and mental health, ego-strength, and all of its subscales, and a negative significant relationship with mental distress. Also, there is a positive significant relationship between ego-strength subscales and total score of it with religious health behaviors and mental health, and a negative relationship with mental distress; (2) The ego-strength can mediate the relationship between religious health behaviors and mental health symptoms and illness.

METHOD

In the present study, the mediating role of ego-strength in the relationship between religious health behaviors and mental health and distress was investigated using structural equation modeling from May 2021 to August 2021. The conceptual model is shown in Figure 1.

The data were analyzed using SPSS 26 and Amos software.

Figure 1: Conceptual model



Participants and procedure

The present study is a descriptive one. The statistical population of the present study was university students. A random sample of 346 university students (M = 23.01, SD = 7.12) participated in the present study. The inclusion criteria were being a student, being literate, not suffering from serious psychiatric or physical disorders, and not having substance dependence. All of the students signed an informed consent document before completing the scales. The students' demographic characteristics showed in Table 1.

Table 1: Study sample characteristics

Measures

Demographics. At the top of the page of the first measure, participants reported their gender, educational levels, marital status, job, and the number of children.

Religious Health Promoting Behaviors Inventory. Religious health-promoting behaviors in participants were measured by the Religious Health Promoting Behaviors Inventory (RHPBI; [32]). It is a 16-item measure that assesses the personal behaviors and habits based on religious doctrines and beliefs in everyday life on a 7-degree scale ranging from 0 (completely disagree) to 6 (completely agree). Cronbach's alpha coefficient for the scale questions was obtained in a sample of 93 individuals (0.88). Convergent and differential validity of the RHPBI was calculated through the simultaneous implementation of the Spiritual Well-being Scale (SWBS; Palutzin and Ellison 1982) and the Mental Health Inventory (MHI; [33]) in the mentioned sample. The results of Pearson correlation coefficients showed that there was a significant positive correlation between the scores of subjects in the RHPBI and SWBS and psychological well-being ranging from 0.37 to 0.49 (P < 0.001) and a negative correlation with psychological distress (-0.33, P < 0.001). These results confirm the convergent and differential validity of RHPBI [32]. In the present study, Cronbach's alpha coefficient for the scale questions was 0.721.

Mental Health Inventory. The mental health of participants was measured using the Mental Health Inventory (MHI-28; [33]). It is a short form of the 34-item Mental Health Scale (Veit and Ware 1983) and it is a 28-item test that has 22 psychological well-being and psychological distress items in a 5-Likert scale ranging from 1 (completely disagree) to 5 (completely agree). The psychometric properties of the 28-item form of the scale were studied. Cronbach's alpha coefficients of psychological well-being and psychological distress for the scores were 0.94 and 0.91. The correlation coefficients between the scores were calculated with a 2-week interval for test-retest reliability assessment. Coefficients for psychological well-being and psychological distress were r = 0.90, r = 0.89, and P < 0.001 respectively. The concurrent validity of the MHI-28 was measured by the simultaneous implementation of the General Health Questionnaire. The results of Pearson correlation coefficients showed that there was a significant negative correlation between the general score of the subjects in the general health questionnaire and the subscale of psychological well-being (r = -0.86, P < 0.001), and a significant positive correlation with the subscale of psychological distress (r = 0.89, P < 0.001) [33]. In the present study, the subscales were consistent internally and Cronbach's alpha coefficients were 0.888 for psychological well-being and 0.903 for psychological distress.

Ego-Strength Scale. The Ego-strength of participants was measured using the Ego-Strength Scale (ESS; [6]). It includes 25 items that have been validated to assess the power of ego in managing and controlling life situations that are difficult. The instrument's items are rated on a 5-degree Likert-type scale ranging from 1 (not at all) to 5 (very much). In several studies in the general (n = 1257) and clinical population (n = 372), the psychometric properties of ESS have been assessed and confirmed [6]. The scale includes 5 subscales (Ego control, ego resiliency, mature defense mechanisms, problem-focused coping strategies, and positive emotion-focused coping strategies). In one study, all subscales were internally consistent and the Cronbach's alpha coefficient ranged from 0.73 to 0.91 [34]. In the present study, all subscales were consistent internally and Cronbach's alpha coefficients ranged from 0.753 to 0.876.

RESULTS

In the present study, the mediating role of ego-strength in the relationship between religious health behaviors and mental health and distress was investigated using structural equation modeling. Using structural equation modeling requires observing the assumption such as normality, outlier data control, linearity, and multicollinearity that need to be met before examining the results of research questions. Kolmogorov-Smirnov test was used to test the normality of the data for each of the research variables. The results showed that the assumption of normality was observed.

The boundary data method was used to evaluate the outlier data. It was indicated that the assumption has been observed. Also, based on Table 2 and 3 data, the assumption of linearity and multicollinearity was found. Based on the assumption of linearity, there must be a linear relationship between the criterion variables and the predictors. So, the results of the correlation matrix indicated that there is a positive significant relationship between religious health behaviors and mental health, ego-strength, and all of its subscales (including ego-control (ECON), ego-resiliency (EROS), mature defensive mechanisms (MDEF), problem-focused coping strategies (PFOC), and positive emotional focused coping (PEMO)), and negative significant relationship with mental distress. Also, there is a positive significant relationship between ego-strength subscales and its total score and religious health behaviors and mental health, and a negative relationship with mental distress. As Table 3 shows, the correlation between all variables was significant (P < 0.001).

Table 2: Descriptive indicators of research variables

Variables	Scale	*M*	*SD*	*V*	Min. score	Max. score
Religious health behaviors	RHPBI	65.04	11.84	140.34	21	98
Psychological well-being	MHI	50.45	9.92	98.43	19	79
Psychological distress	MHI	35.04	10.75	115.74	7	62
Ego-strength	ECON	16.95	3.55	12.65	5	29
	EROS	16.55	3.88	15.12	6	25
	MDEF	15.91	3.81	14.54	6	47
	PFOC	17.33	3.15	9.96	7	25
	PEMO	16.79	3.22	10.43	8	25
	Total	83.55	14.27	203.81	35	120

According to the point that the entering of 2 predictor variables with a correlation coefficient of more than 0.70 in these types of analysis is not allowed, the correlation matrix results were observed. The results showed that there was a noticeable relationship between the criterion and prediction variables, but the relationship was not sufficient for multicollinearity. The highest correlation value was 0.671 for the EROS subscale of ego-strength. Accordingly, all variables were kept in the analysis.

Table 3: Correlation matrix between ego strength, religious health behaviors, mental health, and distress

Variables	1	2	3	4	5	6	7	8	9
Religious health behaviors	1								
Psychological well-being	0.22	1							
Psychological distress	-0.22	-0.48	1						
EROS	.025	0.48	-0.48	1					
ECON	0.32	0.38	-0.36	0.61	1				
MDEF	0.25	0.27	-0.36	0.58	0.55	1			
PFOC	0.28	0.34	-0.29	0.60	0.67	0.45	1		
PEMO	0.30	0.43	-0.30	0.58	0.49	0.42	0.56	1	
Ego-strength	0.35	0.47	-0.45	0.67	0.65	0.66	0.60	0.54	1

P< .001

In reporting the results of structural equations, the main component in examining the fitness of the hypothetical model is the necessary indicators for reporting and the scientific acceptable criteria for confirming these indicators. According to the experts, from all 3 groups of fitness indicators (absolute, adaptive, and purposive), some indicators must be reported (Figure 2).

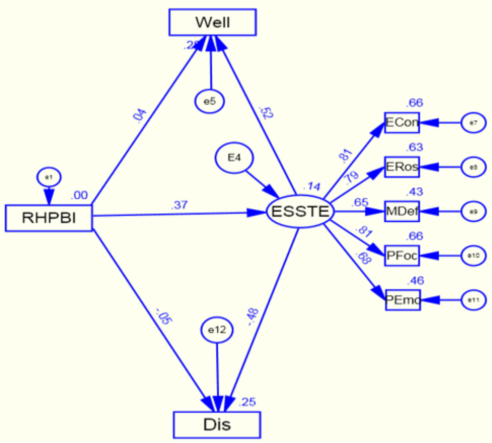

Figure 2: Unmodified hypothetical model of mediating role of ego-strength in the relationship between religious health behaviors and mental health and distress

According to Myers et al. (2006), the numerical value of 3 for the relative chi-square index, the numerical value of 0.60 for root mean square error of estimation, and the numerical value of 0.90 for adaptive indicators are acceptable. Also, for purposive indexes, numerical values greater than 0.50 are suitable. Given the results of Table 4 and the cut-off points of each index, the hypothetical model needed to be modified. The test for fitting the model with observed data, using stepwise selection model correction showed that the model can be corrected: In the ego-strength variable, by creating covariance between the residual error of "ECON and PEMO" indices and the residual error of "EROS and MDEF" markers as well creating covariance between the residual error of mental health and distress (Figure 3).

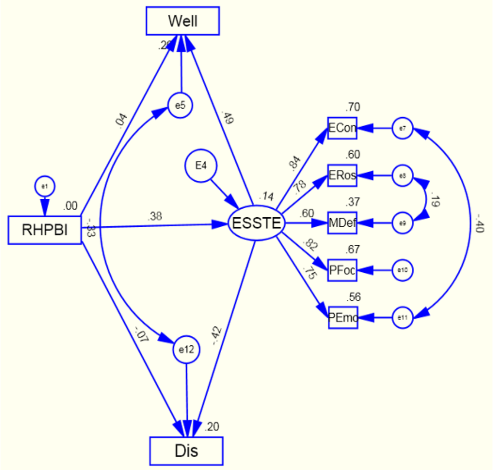

Figure 3: Modified hypothetical model of the mediating role of ego-strength in the relationship between religious health behaviors and mental health and distress

Table 4: Goodness of fit indices of unmodified and modified assumption model

	Absolute indicators				Adaptive indicators			Conventional indicators	
Statistics	Chi	df	Chi/df	RMSEA	GFI	NFI	CFI	PCFI	PNFI
Unmodified	135.80	20	6.79	0.130	0.896	0.880	0.895	0.639	0.628
Modified	72.507	17	4.265	0.210	0.950	0.936	0.950	0.557	0.568

As Table 4 shows, the modifications made on the hypothetical model resulted in a 3-degree decrease in the degree of freedom in the modified model, and a 63.294-degree decrease in the chi-square value, resulting in a 2.535-degree decrease in the relative chi-square value. Therefore, in the modified model, indicators of absolute fit indices along with other indicators such as root mean squared error of approximation with a confidence interval of 0.90, adaptive indicators (GFI, NFI, and CFI) with a cut-off point of 0.90, and the indicators (PCFI, and PNFI) with a cut-off point of 0.60, are in a desirable condition. It indicates that the hypothetical modified model is valid.

The results of the modified model show that the ECON subscale with a coefficient effect of 0.84, had the maximum contribution and the MDEF subscale with a coefficient effect of 0.60, had the minimum contribution in the score of ego-strength. The factor loadings of all paths were significant in the hypothetical model. The results also indicated that the direct effect of religious health behaviors on mental health and distress were respectively 0.4 and -0.5. Based on these results, it can be said that religious health behaviors have had a positive non-significant effect on mental health and a negative non-significant effect on mental distress.

To investigate the statistical significance of the indirect effect of religious health behaviors on mental health and distress through ego-strength (the mediating role of ego-strength on the relationship between religious health behaviors and mental health and distress), the Bootstrap method was used.

The results showed that religious health behaviors have affected mental health through ego-strength 0.185. The result is significant statistically (P = 0.001) and suggested that with one unit increase in religious health behaviors, 0.185 units will add to the mental health scores. The results also suggested that religious health behaviors have affected mental health and distress through ego-strength -0.159 The amount is significant statistically (P = 0.001) and suggested that with a unit increase in religious health behaviors, 0.159 units will decrease in the mental distress.

DISCUSSION

The COVID-19 pandemic is one of the risk factors for psychological diseases. COVID-19 related post-traumatic stress symptoms are correlated to distress, anxiety, and low sleep quality [35]. Furthermore, during and after traumatic events, depression has been increased [36], but during the COVID-19 pandemic, the increase is more than in previous traumatic events.

One of the mechanisms through which ego-strength can affect mental health and illness symptoms is resilience (one of the ego-strength components) during the COVID-19 pandemic. Resilience is the dynamic process of adapting positively to hard and negative experiences [37]. Using this feature probably enhances one's ability to manage conflicts.

Ego-strength has an important role in predicting health and reflects the attitudes toward problems, responding to failure, and the ability to adapt to one's emotional status. Also, ego-strength plays a predictive role in health conditions and the therapeutic alliance in chronic problems [38]. Ego-resiliency can moderate the association between cortisol level and emotional labor [39].

Another mechanism through which ego-strength can influence symptoms of mental health and illness is the use of enhanced defensive strategies in the COVID-19 pandemic. Defensive mechanisms are responsible for protecting the individual against anxiety and awareness of the dangers and causes of internal and external stress. Ego-strength enhances problem-solving skills [40], and using these effective strategies to cope with stress can increase mental health.

Maladaptive and adaptive coping can moderate the association between life events and mental health problems [41]. Coping strategies moderate the association between job insecurity and mental health [42]. Empowerment helps the individual to manage stressful situations to some extent by using adapted emotion regulation strategies [6].

There has been some research on the relationship between ego-strength dimensions and depressive disorders that support the finding of the present study [43]. In interpreting the finding, we can note the relationship between ego-strength and psychopathology. Ego-strength is one of the key components of psychodynamic models for explaining psychological trauma. Low ego-strength makes the individual unable to perform the reality test properly, increasing interpersonal and intrapersonal conflicts [44]. Therefore, the development of mental disorders seems to be related to low ego-strength. Low ego-strength is associated with dysfunctional defensive mechanisms, lack of adaptive capacity to defeat, and low level of arousal. One of the main syndromes reflected in the functioning of neurotic patients and personality disorders is the low level of ego-strength and poor defensive mechanisms [7].

Ego control, the ability to control and manage situations is another component of ego-strength [45]. Under controlled individuals have some characteristics such as self-dramatizing, unpredictable, and unable to delay gratification, assertive, moody, rebellious, and self-indulgent. Over controlled individuals have some characteristics such as being consistent, bland, calm, and dependable. Resilient individuals have some traits like having a high level of aspiration and wide interests, socially poised and skilled, assertive, and cheerful, and neither lacking personal meaning in life, emotionally bland nor self-defeating [46].

Limitations and Future directions

There are some limitations in the present study which are worth acknowledging. The findings are derived from a cross-sectional method that can influence the results, and causal interpretations of the findings are speculative. The issues of causality could best be investigated through longitudinal surveys. The present study was conducted only on university students (most of them were young), and the generalization of the findings to less-educated persons should be done with caution. Also, the findings may not fully generalize to other countries, because of the diverse cultural and socioeconomic factors. Furthermore, due to the higher number of female students in some universities, the number of women in the present study is much higher than men. Therefore, this point should be taken into account when generalizing the results. Future studies can explore similar questions in other samples such as subjects with various diseases, different group ages, various education levels, and different socioeconomic and cultural environments. The ego-strength is a novel variable that is not yet well known and needs a lot of research attempts to understand it and the various roles it can play. There may be many other variables that can mediate the relationship between religious health behaviors and mental health and illness and can be explored in future research. Finally, there may be other alternative hypothetical models that had not been evaluated which would fit the data well or even better. Future research can test alternative or more complex models for the present variables.

CONCLUSIONS

In conclusion, the current study provides evidence that ego-strength can mediate the relationship between religious health behaviors and mental health symptoms and illness. Also, the results showed that there is a positive relationship between religious health behaviors and mental health, ego-strength, and all of its subscales, and a negative relationship with mental distress. Furthermore, there is a positive relationship between ego-strength subscales and their total score and religious health behaviors and mental health, and a negative relationship with mental distress during the Covid-19 pandemic. The data provides new insights into the importance of ego-strength in the religious health psychology area. Mental health and religious health behaviors are both very important psychological variables. The present study helped to clarify the relationship between these variables. Any practical effort to reinforce ego-strength can help strengthen the relationship between mental health and religious health behaviors. Everyone can benefit from the results of the present study.

Ethical Approval

All procedures performed in studies involving human participants were under the ethical standards of the institutional and/or national research committee and the 1964 Helsinki declaration and its later amendments or comparable ethical standards.

Informed Consent was obtained from all individual participants included in the study.

Conflict of interest

All authors declare that they have no conflict of interest.

CLINICAL PRACTICE

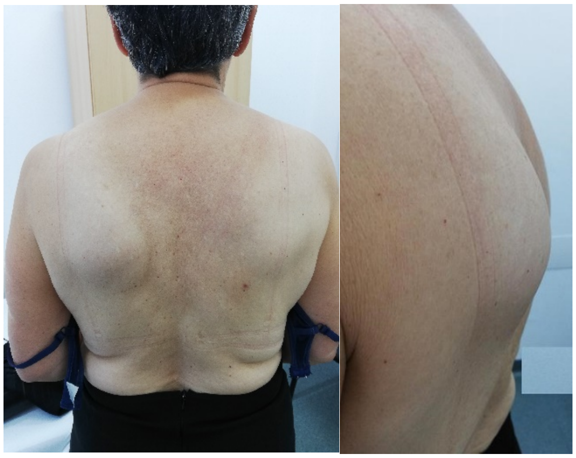
Elastofibroma – an uncommon cause of upper limbs pain

Natalia Dumitrescu[1], Bianca Sandu[2], Silviu V. Dumitrescu[2]

A female patient age 65 came to our clinic forcontinuous pain of the upper limbs (left more than right), increased when moving the scapulae. Patient declared that in the past few months the dorsal decubit became gradually painful and she cannot achive a good sleep. One year ago patient was diagnosed with bilateral suprascapular lipoma and a surgical removal was proposed.

At the visual examination, we found two well-circumscribed suprascapular tumor mobile with arms movements. At palpation, we noticed that each scapula was pushed from below from an underlying tumor with a very firm consistency.

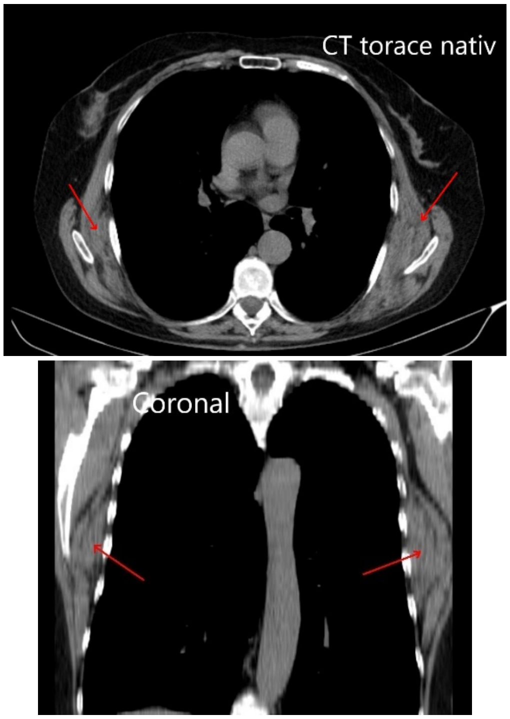
Figure 1: Clinical aspects



Chest radiography was normal.

A CT scan of torax was performed and revealed two subscapular unencapsulated, soft tissue masses with skeletal muscle attenuation interspersed with strands of fat attenuation [1, 2].

Figure 2: CT aspects



The patient was directed to thoracic surgery and the tumors were removed. The histological findings were consistent with the diagnosis of elastofibroma [3]. The recovery period was long, allmost two months passed before complete healing.

The long period needed for healing, usually burdened with local complications and the fact that the tumor is benign makes the surgery not recommendable for the patients with no discomfort or impared arms movement [4].

Elastofibroma dorsi: clinical experiences of 19 cases

Hacer B. Yesilcay[1], Sencan Akdag[1]

Abstract: *In this study, symptoms, functions, and outcomes of patients who underwent surgery with the diagnosis of Elastofibroma dorsi between 2007-2019 in our clinic were discussed retrospectively.*

A total of 19 patients were operated on with the diagnosis of Elastofibroma dorsi in our clinic. The demographic characteristics of patients such as age and gender, symptoms, clinical findings, diagnostic and radiological features, surgical procedures, results of surgical treatments, and postoperative follow-up results were evaluated based on the records.

The mean age of patients who underwent surgery was 55.7 and there were 13 females and 6 males. The most common clinical complaint was swelling (61%). Seven of ED were located on the right side, 3 of them were located on the left side and 7 of ED were located bilaterally. The mass in all cases was over 5 cm in diameter, complete surgical excision was done via muscle-sparing technique. All patients were followed up postoperatively and there was no recurrence.

ED should be considered in terms of differential diagnosis when middle-aged patients present with a mass in the scapular region and shoulder pain. Total excision is surgically sufficient in symptomatic patients.

Keywords: *elastofibroma dorsi, shoulder pain, chronic back pain*

INTRODUCTION

Elastofibroma dorsi is a benign, rarely seen, slow-growing soft tissue lesion. First described by Jarvi and Saxen in 1961. The lesion is usually located at the inferior angle of the scapula., deep to the serratus anterior, and may be attached to the periosteum of the ribs [1]. The etiology is not known clearly [2]. Symptoms are usually chronic back pain, stiffness, swelling, snapping of the scapula, and increased pain during shoulder movement. Noninvasive imaging methods such as ultrasonography, computed tomography, and magnetic resonance imaging are used in the diagnosis of elastofibroma dorsi [3]. Total excision is the best treatment to prevent relapses and relieve symptoms [4]. In this study, we describe our experience of diagnosing and treating elastofibroma dorsi patients between 2007-2019.

METHODS

Between 2007 and 2019, 19 patients operated with the diagnosis of elastofibroma dorsi were retrospectively reviewed. The cases were evaluated in terms of age, gender, complaints, clinical findings, diagnostic and radiological features, surgical applications, surgical treatment results, and postoperative follow-ups. The radiological examination was applied by ultrasonography, thorax computed tomography (CT), and magnetic resonance imaging (MRI).

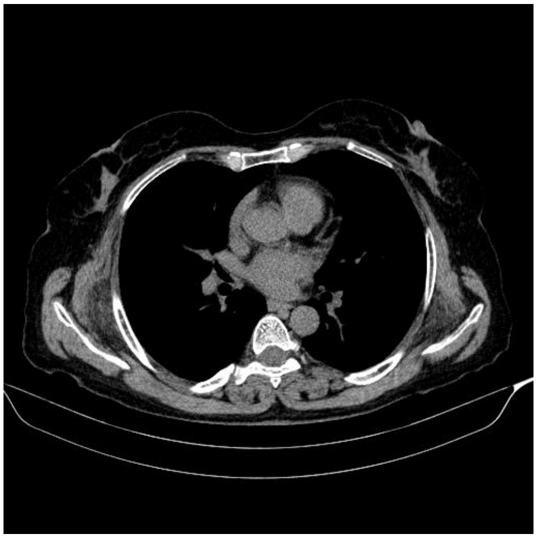
The mass diameters of all cases were measured by radiological evaluation. None of the cases were directly diagnosed by biopsy. Excision was undertaken in all cases after pre-operative consent was obtained. A transverse or parabolic incision at the inferior pole of the scapula was used. All operative samples were sent for histopathological evaluation. The cases were followed up in six-month periods after surgery.

RESULTS

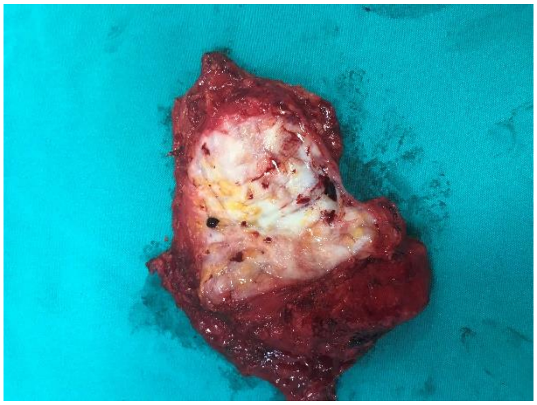
13 of the cases were female (69%), 6 were male (31%) and the mean age was 55.7 (31-68) years. The most common clinical complaint was swelling (61%). Other complaints were chronic back pain (31%), snapping of the scapula (23%), and increased pain with shoulder movement (19%). In our series, 27% of cases were found to be asymptomatic. The mean duration of symptoms was 20 months (3 to 96). The lesion was located in the subscapular region in all of the patients, being unilateral in ten and bilateral in nine. Of the unilateral tumors, three lesions occurred on the left side and seven on the right. The radiological examination was applied by ultrasonography and thorax computed tomography (CT) for all patients (Figure 1). Magnetic resonance imaging was applied in 7 cases that could not be evaluated adequately by thorax computed tomography.

Figure 1: CT scan image of a patient



In all cases, total excision of the lesion was provided via muscle-sparing technique then, hemovac drain which was removed 24-72 hours after the operation was placed in the subscapular area and the layers were closed following the anatomy. All excised samples were sent for pathological examination. In the pathological examination macroscopically, solid lesions were observed with a yellow and white cross-section surface covered with fibrous capsule and containing adipose tissue (Figure 2). In the microscopic examination of hematoxylin-eosin sections, mature adipocytes and elastic fibrillar stained positive with Von Gieson were observed. Postoperative complications developed in four (21%) of operated cases; in one (5%) case antibiotic allergy was observed and in three (16%) cases seroma requiring needle aspiration was observed. The mean length of hospital stay was 4 days (2 to 8) and the mean follow-up was 5 months (3 months to 2 years). No recurrence was observed during the follow-up period.

Figure 2: Solid lesions with a yellow and white cross-section surface covered with a fibrous capsule and containing adipose tissue



DISCUSSIONS

Elastofibroma dorsi is a benign, unencapsulated, slow-growing soft tissue tumor, is usually seen in women, in the 5th and 6th decade of life. First described by Jarvi and Saxen in 1961 [1]. Despite it is traditionally considered to be rare, Jarvi and Lansimies showed, in a series of 235 postmortems in patients older than 55 years, changes in the subscapular thoracic fascia similar to elastofibroma in 24.4% of women (29 of 119) and 11.2% in men (10 of 89) [5]. The age and gender of patients in our series were consistent with the literature.

ED is often localized in the subscapular region which is between the rhomboid and latissimus dorsi muscles and the sixth and eighth ribs. However, other localizations such as deltoid muscle, foot, greater trochanter, olecranon, cornea, stomach, greater omentum, ischial tuberosity, intraspinal space, and chest wall have been reported in the literature [2, 6, 7].

ED is often unilateral and right-sided. The number of bilateral cases is around 10-60%. Bilateral cases can be developed synchronously or asynchronously [8]. In our study, the lesion was located in the subscapular region in all of the patients, being unilateral in ten (52,7%) and bilateral in nine (47,3%). 16 of the 28 ED lesions were localized on the right side (57,1%). Lesions were synchronously detected in patients with bilaterally located elastofibroma dorsi.

The pathogenesis of ED is not clear, several hypotheses have been put forward. Repeated micro-injuries between the chest wall and the scapula, the source of excess elastin production, and collagen degeneration could play a physiopathological role in this rare lesion [9].

This view has been supported by the higher ED prevalence particularly among individuals who work at hard manual labors. However, patients who have never been involved in hard manual work, as well as those with elastofibromas in different locations, have undermined this view. In our study 3 patients (15,7%) were manual laborers. The rest of the cases did not have heavy labor history or heavy sporting activities in their anamnesis records.

In a study investigating genetic anomalies in ED cases, changes in DNA copy number were observed in tumor tissue, mainly in the chromosome Xq12-q22 and 19 regions [10]. In a cytogenetic study by Mc Comb et al., they detected genetic instability in chromosome number 1 and translocation in number 8-12, stated that they may be neoplastic, not reactive, due to these clonal abnormalities. In the largest reported series of 170 patients with the lesion, a familial predisposition was suggested with 32% having a positive family history for elastofibroma [8]. In our study, none of the patients had a family history of ED.

There are also opinions such as reactive fibromatosis, degeneration due to vascular insufficiency, elastotic degeneration, and enzyme defect [8].

Clinical findings are mostly related to the size of the lesion. They often grow slowly and are asymptomatic. As the lesion grows, there is swelling in the back, increased pain with shoulder movements, snapping of the scapula, and chronic back pain [11]. In our series, the most common clinical complaint was swelling (61%), 27% of cases were found to be asymptomatic.

Imaging modalities for diagnosis include ultrasonography, CT, and MRI. Solivetti et al. reported that the use of diagnostic USG is an adequate and inexpensive method [12]. Kransdorf et al. reported that radiological evaluation with MRI or CT is compatible with histopathological evaluation [13]. The most important imaging modality is accepted as an MRI. Malghem et al. reported that fibrous tissues within the mass have similar signal characteristics with the surrounding muscle tissues in the MRI examination, while fat tissue has higher signal characteristics than the mass, and these findings are pathognomic for the mass [14]. In our study, the radiological examination was applied by ultrasonography and thorax CT for all patients. MRI was applied in 7 cases that could not be evaluated adequately by thorax computed tomography. In our series, radiological findings were compatible with the literature.

Lipoma, neurofibromas, metastatic lesion, primary or metastatic sarcoma, fibrosarcoma, synovial sarcoma, the desmoid tumor should be considered in the differential diagnosis. Needle aspiration or incisional biopsy may be performed to eliminate the possibility of malignancy. However excisional biopsy is often preferred due to diagnostic radiological evaluation's sufficiency [15, 16]. In our series, a needle biopsy wasn’t performed.

Macroscopically, ED is in the form of a fibrous lesion of dirty white color, is non-encapsulated, and contains streaks of fat tissue. Some elastofibromas may have cystic degeneration. The histological appearance of the lesion is typical. In large areas, it contains hyalinized collagenous stroma and little amount of fat tissue in between. In hypocellular collagenous stroma, fibrils [6] and globules that show eosinophilic staining are striking. In sections of hemotoxylin-eosin, the presence of fibrils and globules is important for determining the location of the lesion and its diagnosis [4, 9].

Elastofibroma dorsi is treated with total excision, but surgery is not recommended for asymptomatic lesions smaller than 5 cm [17]. In our series, the mass in all cases was over 5 cm in diameter, complete surgical excision was done via muscle-sparing technique, which requires preparation of latissimus dorsi and serratus anterior muscle flaps.

The most common complications after surgical excision are hematoma or seroma. Therefore, after excision of the mass, the bleeding control should be performed cautiously [11]. In this study, we used hemovac drainage and a compression bandage to reduce these complications. Postoperative complications developed in four (21%) of operated cases; in one (5%) case antibiotic allergy was observed and in three (16%) cases seroma requiring needle aspiration was observed.

Local recurrence after total excision is rare and malignant transformation has not been reported. In the first recurrence, total surgical excision can provide a cure, but in subsequent recurrence, total excision may not be performed [9]. In our cases, no recurrence was detected during the follow-up period.

As a result, ED should be considered in terms of differential diagnosis when middle-aged patients present with a mass in the scapular region and shoulder pain. Total excision is surgically sufficient in symptomatic patients.

Electrodiagnostic studies in carpian tunnel syndrome

Hazim Elayan[1], Ana M. Oproiu[2], Radu C. Jecan[2], Ioan P. Florescu[2]

Abstract: *The diagnosis in Carpian tunnel syndrom is based on clinical symptoms and electrodiagnostic studies. Electrodiagnostic studies help to stage both motor and sensory nerve damage.*

Keywords: *electrodiagnosis, nerve conduction, motor nerve, sensory nerve*

INTRODUCTION

Electrodiagnostics represents a test or a paraclinical study of analysis of the muscular and nervous system, which evaluates the transmission of the motor and sensory nerve impulse, respectively, which helps the specialist doctor to obtain a diagnosis or prognosis, after the anamnesis and clinical examination have been performed [1].

When we talk about electrodiagnostics we refer to both Electromyography (EMG) and Electroneurography (ENG) [1].

Figure 1: Electrodiagnostics (https://share.upmc.com/2017/09/facts-electrodiagnostic-medicine/)

There are several advantages of electrodiagnostic [2]:

1. May specify the location of the neurological or muscular injury.

2. Can provide data on the type and severity of the lesion (demyelinating, axonal or mixed lesion).

3. It can specify the degree of axonal injury (neurapraxia, axonotmezis, neurotmezis).

4. It can stage affection (acute, subacute, chronic stage).

5. Can diagnose and monitor the progress of the disease over time.

6. It can formulate a prognosis of the disease and can be used in monitoring the effects of treatment (radiculopathy).

7. Represents an objective method of investigating the neuro-muscular system.

Limitations of electrodiagnostic studies

In chronic nerve compression, the first changes that occur in nerve fibers are changes in demyelinated nerve fibers, which cannot be evaluated with electrodiagnostic studies and tests [3]. Example: early symptoms of pain and paresthesia cannot be objectified with electrodiagnostic studies [4].

Another limitation of the nerve conduction study is the location of the nerve lesion in the extremity. Nerve problems occur very distally or very proximal and are difficult to assess [4].

Dynamic changes in blood flow that may intermittently cause changes in peripheral nerve function may not be detected with electrodiagnostic studies [4].

The timing of nerve conduction velocity studies also influences their usefulness because even complete sectioning of the nerves will not become evident for 26

Corresponding author: Hazim Elayan
hazim.elayan@gmail.com

[2] "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania

weeks after injury [4].

In situations with more than one level of injury or when systemic polyneuropathy is present, nerve conduction studies may be less reliable [4].

Electrodiagnostic studies in carpal tunnel syndrome

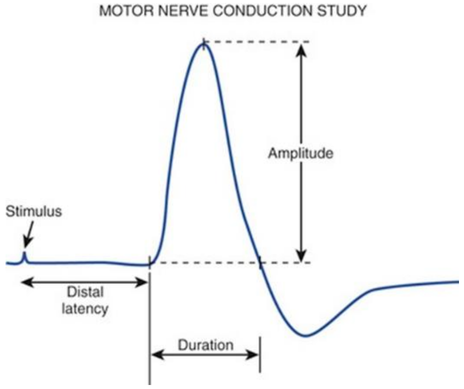
Electroneurography (ENG)

1. Nervous motor conduction:

The median nerve is electrically stimulated at the wrist and the motor response from the short abductor muscle of the thumb is recorded, with the help of surface electrodes; usually, the motor response occurs 4 msec after the application of the stimulus, an interval called motor distal latency (DL) (latency is the time required for the impulse to travel the distance from the stimulation site to the collection site); if a distal latency over 4.5 msec is observed, it means that we are dealing with a carpal tunnel syndrome [5, 6, 7].

Nerv conduction velocity ($NCV = s/t = S/PL - DL$)[1] in the motor nerve fibers is 45 - 65 m/s, in the nerve fibers, depending on the thickness of the nerve (Figure 2).

Figure 2: Compound muscle action potential (CMAP). Distal latency is measured from the stimulus to the onset of the negative response. The amplitude is measured from the base value to the negative peak (https://musculoskeletalkey.com/the-electrodiagnostic-examination/; Jinny Tavee, Kerry H. Levin)



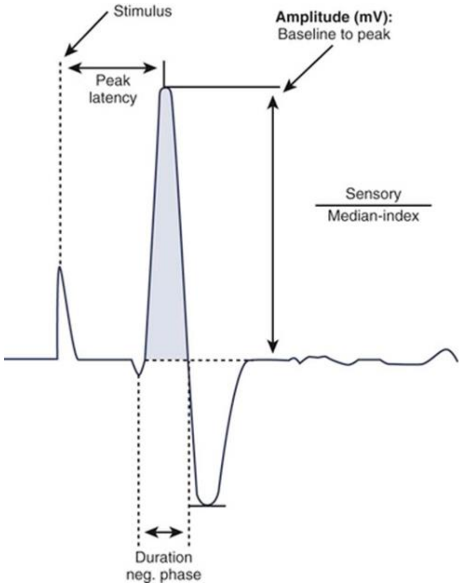
Observation: It can also stimulate the median motor nerve both palmar and at the wrist, evaluating the amplitude of the motor response thus providing information on the lesion: conduction block or axonal lesion [5, 6, 7].

The two-point stimulation method is preferred because it has the advantage that it eliminates the inaccuracies generated by the fact that the measured time represents not only the conduction in the nerve fiber, but also the conduction through the motor plate.

2. Nervous sensitive conduction:

Most frequently, it is measured antidromically, electrically stimulating the median nerve in the wrist and recording with surface electrodes in the fingers (most often, in the index and middle); a decrease in the sensitive conduction velocity (obtained by dividing the distance between the stimulator cathode and the active recording electrode at the sensitive distal latency) below 40 m/s is diagnostic for carpal tunnel syndrome [5, 6, 7].

Figure 3: Sensory nerve action potential (SNAP). The peak latency is measured at the beginning of the negative phase. The amplitude is measured from the base value to the negative peak (https://musculoskeletalkey.com/the-electrodiagnostic-examination/; Jinny Tavee, Kerry H. Levin)



Another method applied when the changes are smaller is to stimulate from the same distance the ulnar and median nerves at the wrist, with the recording of the response from the IV finger – ring, which has mixed sensory innervation; a distal latency when stimulating the median nerve by more than 0.5 msec higher than when stimulating the ulnar nerve has diagnostic significance [5, 6, 7].

Electromyography (EMG)

When the existence of an axonal suffering of the median nerve is suspected, by prolonged compression, electromyography with needle is performed of the short abduction muscle of the thumb to detect early (before the installation of clinically obvious amyotrophy) the denervation changes; in this case, surgery is mandatory [5, 6, 7].

---

[1] S = distance, t = time required for the impulse to move between the two stimulation points

Muscles are also tested electromyographically, when necessary for differential diagnosis (radial flexor of the carpus – median nerve injury above the carpal tunnel; adductor police – ulnar nerve injury, upper thoracic opening syndrome, etc.) [5, 6, 7].

CONCLUSIONS

Electrodiagnostic studies include electromyography (EMG) and nerve conduction studies.

Tests are not a substitute for a detailed clinical examination by a specialist.

Unfortunately, some doctors rely on these studies without recognizing the major limitations of electrodiagnostics examination [8].

Electrodiagnostic studies are useful to eliminate others associated problems such as cervical disc disease, motor neuron problems, myopathy or overlapping polyneuropathy.

Emergency surgery for complicated colorectal cancer – What we choose: a retrospective cohort study

Georgiana B. Constantin[1], Dorel Firescu[2,3], Dragoș Voicu[2], Bogdan Ștefănescu[2,3], Raul Mihailov[1], Cristina Șerban[2,3], Eugenia Panaitescu[1], Rodica Bîrlă[1,4], Silviu Constantinoiu[1,4]

Abstract: *Introduction: Despite the progress that has been made regarding the diagnosis, a worrying percentage of patients are still admitted in an emergency, with complicated colorectal tumors, which often require interventions without a curative visa. The study aims to analyze the factors involved in choosing the type of surgical treatment.*

Patients and methods: We included in the study a group of 431 patients admitted and operated in an emergency for complicated colorectal cancer in the Surgery II Clinic of the Clinical Emergency County Hospital "Sf. Ap. Andrei" from Galați, between 2008-2017. We retrospectively analyzed the patients' data and we made statistical correlations between the type of emergency surgery and epidemiological, clinical, paraclinical, and intraoperative factors.

Results: Colostomy was mainly practiced in older patients ($p<0.01$), from rural areas ($p<0.01$), with associated cardiac diseases ($p<0.01$), with hydro electrolytic disorders ($p<0.03$), rectal tumors ($p<0.01$), peritoneal carcinomatosis ($p<0.02$), frozen pelvis ($p<0.01$). Hartmann's operations were associated with patients with: leukocytosis ($p<0.01$), intestinal perforation ($p<0.01$), sigmoid tumors ($p<0.01$). Internal derivations were associated with patients with: liver metastases ($p<0.01$), splenic angle tumors ($p<0.01$), tumors invading other organs ($p<0.01$), and stage IV of the disease ($p<0.01$). Resections with anastomosis were associated with transverse colon tumors ($p<0.01$), well-differentiated tumors ($p<0.01$).

Conclusions: The type of emergency surgery performed correlated well with the age of patients, the area, the comorbidities, the history of the disease, cachexia, anemia, oligoanuria, hydroelectrolyte disorders, tumor complication, and location of the tumor, hepatic metastases, and tumors' invasion in other organs, tumor grading and stage of the disease.

Keywords: *surgical treatment, colorectal cancer, emergency, correlations*

INTRODUCTION

In Romania, according to the GLOBOCAN 2012 analysis, colorectal cancer was the second [1]. According to the data provided by the GLOBOCAN 2018 statistics, colorectal cancer ranks third in incidence globally (after lung and breast

birlarodica@yahoo.com

cancer) and at the 2nd place as cancer mortality (after lung cancer) [2].

The incidence is increasing both in developed countries and in those where until a few decades ago, the colorectal cancer was not a major concern [1].

Both sexes are affected in approximately equal proportions and the most affected decades of age are the sixth and the seventh [1].

Despite the improvements that have been made regarding the diagnosis and the possibilities of screening, a worrying percentage of patients are still admitted in an emergency, with complicated colorectal tumors, which often require interventions without a curative visa [3].

Of all the complications of colorectal cancer, the intestinal occlusion is the most frequent and it occurs especially in the case of tumors located in the left colon and rectum [4].

There are no clearly established protocols regarding the choice of the type of emergency surgery for colorectal cancer. Various standardizations have been tried, but no consensus has yet been reached [5]. The most debated issue is the choice of the optimal intervention for occlusive left colon cancers [6].

The choice of the surgical treatment method in an emergency is made according to several factors, such as the biological status of the patients, the duration of the complication, comorbidities, age, local invasion of the tumors, the presence of metastases, the appearance of the affected colon. Whenever possible, it is ideal to choose a method that involves the tumor resection or allows it in a second time [7].

The most recent recommendations of the WSES Scientific Committee indicate in the case of occlusive or perforated colon tumors to practice a right hemicolectomy with a terminal ileostomy. The right hemicolectomy with ileocolic anastomosis can be performed if there is no significant increase in operative time and good bowel vascularization. For left colon occlusive tumors, the Hartmann operation is considered the procedure of choice. In patients with severe instability, a colostomy should be performed. For perforations on the left colon, Hartmann's procedure is recommended, with the mention of considering the open abdomen [8].

PATIENTS AND METHODS

We included in the study a group of 431 patients admitted and operated in an emergency for complicated colorectal cancer in the Surgery II Clinic of the Clinical Emergency County Hospital “Sf. Ap. Andrei” from Galați, between 2008-2017.

The patients’ data were collected from observation sheets, operating protocols, and pathological exams. The following epidemiological and clinical factors were analyzed: age, sex, provenance area, hereditary-collateral history, abdominal surgical history, comorbidities, preoperative diagnosis, and clinical status at admission (weight, height, diuresis).

We analyzed the following paraclinical factors: the values of hemoglobin, hematocrit, leukocytes, platelets, and ionograms at admission. Among the therapeutic factors, we analyzed the tumor location, the invasion in other organs, the intraoperative appearance of the frozen pelvis, the presence of hepatic metastases and peritoneal carcinomatosis, the type of surgery performed in an emergency, lymph node dissection, liver biopsy, stoma reversal after Hartmann procedure.

The inclusion criteria were patients with colorectal malignancies hospitalized and surgically treated in the Surgery II clinic of the Clinical Emergency County Hospital “Sf. Ap. Andrei" from Galați, between 2008-2017, patients over 18 years old.

The exclusion criteria were patients with benign colorectal pathology, patients with malignant colorectal tumors operated electively, patients whose observation sheets no pathological reports were attesting the type of tumor, grading, and classification in the pTNM system were not found.

Study design

Epidemiological, clinical, paraclinical, and therapeutic factors were retrospectively analyzed, to correlate them with the four types of surgery (external derivations, Hartmann procedure, internal derivations, and resections with anastomosis).

Statistical analysis

Using the SPSS version 23.0, statistical correlations were obtained, indicating the p-value with the Pearson, Chi-Square, and Likelihood Ratio tests. Statistical conclusions were formulated using a statistically significant difference threshold the value $p < 0.05$ for all calculations performed.

RESULTS

In each of the 10 years included in the observation period of this study, an average of 43 patients was hospitalized and operated in an emergency.

There have been practiced 179 (41.5%) external derivatives (of which 158 colostomies and 21 Pezzer cecostomies), 134 (31.1%) Hartmann operations, 29 internal derivatives (of which 16 ileo-transverse, 9 transverse-descending, 2 ileo-sigmoid, 1 ileo-descending, and 1 transverse-sigmoid anastomosis) and 89 (20.9%) resections with anastomosis (of which 47 right hemicolectomies, 13 left hemicolectomies, 26 transverse/sigmoid/descending segmental colectomies, 1 subtotal colectomy, 1 ileo-transverse anastomotic resection for a relapsed tumor and 1 rectal tumor resection with mechanical anastomosis).

The sex distribution of patients in the study reveals the predominance of men, with a ratio M/F = 256/175. Comparing the types of surgery performed (1 - colostomy/ cecostomy, 2 - Hartmann, 3 - internal derivations, 4 - resections with anastomosis), no association with the sex of the patients is obtained.

In the studied group, the patients from the urban area predominated. Patients in rural areas were associated with a colostomy ($p<0.01$) (Table 1).

Most patients (55.92%, n = 241) included were in the 5th and 6th decades of age. An association of the advanced age of the patients with the colostomy is noted ($p<0.01$) (Table 1).

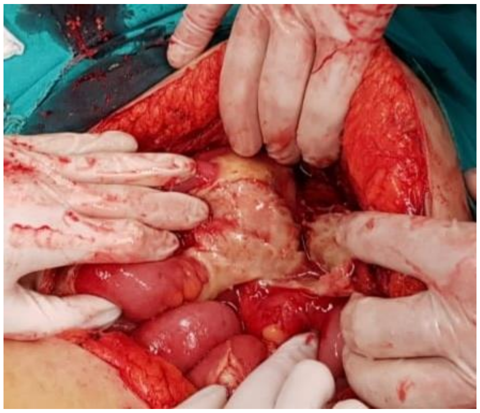
43 (9.97%) of the patients had a significant hereditary-collateral history, as follows: 19 had a brother/sister with colorectal cancer, another 18 patients had a father diagnosed with colon or rectal cancer, and six patients had a son with colorectal cancer. Patients with a significant heredocolateral history for colorectal cancer were associated with colostomy and with Hartmann's procedure ($p<0.02$) (Table 1).

174 patients (40.37%) had a personal history of abdominal surgery, as follows: appendectomy - 72 patients, hysterectomy - 31 patients, cholecystectomy - 29, gastric resections (for gastroduodenal ulcer disease) – 12, caesarean section - 8, splenectomy (post-traumatic spleen rupture) -6, nephrectomy (renal lithiasis) - 6, segmental colectomy (descending colon cancers) - 4, right hemicolectomy - 2, adnexectomy - 2, hepatic hydatic cyst operated - 1 patient and colon esophagoplasty (for accidental ingestion of sodium hydroxide in adolescence) -1 patient. Comparing the patients with or without a surgical history, no statistical associations are found with the type of surgery.

Most patients (51.04%) included in the study had comorbidities. 148 of the patients (34.33%) had associated cardiac pathology, of which 77 (17.86%) with high blood pressure, 38 (8.81%) with atrial fibrillation with chronic anticoagulant treatment, 8(1.85%) with a history of myocardial infarction, 13 (3.01%) with varying degrees of heart failure, 12 (2.78%) with ischemic stroke; 42 (9.74%) patients were diabetic; 9 (2.08%) patients were diagnosed with liver cirrhosis, with thrombocytopenia; 9 other patients had colonoscopically diagnosed colon pathology, 5 of whom had colonic polyposis, 3 with Crohn's disease and one with diverticulosis. 2 of the patients had active pulmonary tuberculosis at the time of admission (transferred from another hospital). We also found statistical association by correlating the type of surgery with the presence of heart disease and atrial fibrillation, but not with liver cirrhosis. Thus, in patients with cardiac disease or atrial fibrillation, type 1 surgery (colostomy) was performed ($p<0.01$), respectively ($p<0.01$) (Table 1).

The majority of patients (87.94%, n = 379) had as main symptoms at admission the abdominal pain and the disorders of intestinal transit, and the rest (12.06%, n = 52) presented with rectal bleeding. Regarding the beginning of the symptomatology, the majority of patients (58%, n = 250) had symptoms (intestinal transit disorders and rectal bleeding) that they neglected. In patients with neglected symptomatology, it was performed a Hartmann procedure or colostomies ($p<0.01$). Patients with abdominal pain and intestinal transit disorders were associated with colostomy/ Hartmann ($p<0.01$) (Table 1).

Figure 1: Perforated sigmoid tumor (Surgery Clinic II of the County Hospital of Emergency Clinic „Sf. Ap. Andrei „Galati)



The preoperative diagnosis was intestinal obstruction in 332 patients (77.03%); 36 patients (8.35%) had intestinal perforation (tumor/diastatic) (Figure 1), 14 (3.25%) with imminent diastatic perforation (Figure 2) and 49 (11.37%) had rectal bleeding. Patients with hemorrhage or with imminent intestinal perforation (tumor/diastatic) at admission were associated with a colostomy; patients with intestinal occlusion were associated with internal derivations and resections with anastomosis. Patients with intestinal perforation were associated with the Hartmann procedure (p<0.01) (Table 1).

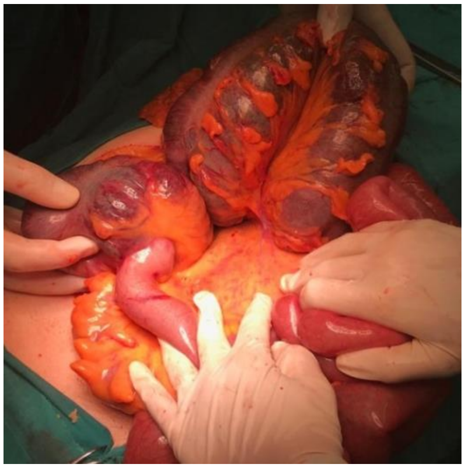
Figure 2: Rectosigmoid tumor with necrosis and imminence of diastatic perforation (Surgery Clinic II of the County Hospital of Emergency Clinic „Sf. Ap. Andrei „Galati)



All patients benefited from preoperative imaging investigations, such as empty abdominal radiography and for those with a clinical diagnosis other than intestinal obstruction, abdominal ultrasonography was performed.

128 patients (29.69%) presented with cachexia when admitted (BMI <18.5). 114 patients (26.45%) had oliguria at admission (diuresis <= 500 ml). We found statistically significant differences in the cases of cachectic and oliguric patients at admission. In these patients, the colostomies were mainly practiced and only in very few cases the internal derivations/resections with anastomosis were chosen (p<0.01) (Table 1).

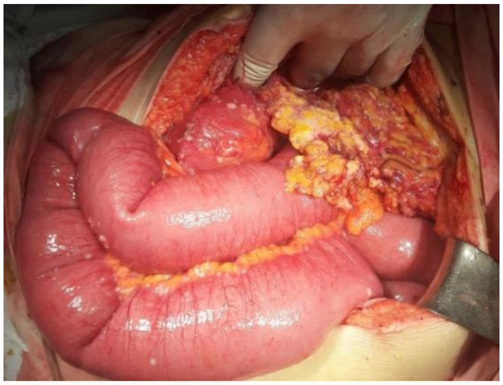
299 (69.37%) of all patients had anemia at admission. Of these, 107 required full blood transfusions or erythrocyte mass. According to the reference interval of our laboratory, we considered anemia values of hemoglobin less than 11g/dl and hematocrit less than 35%. Statistical analysis revealed the association of patients with anemia with a colostomy, and Hartmann's operations (p<0.01); as well as patients with anemia with blood transfusion with a colostomy, or internal derivations (p<0.02) (Table 1).

63 patients (14.61%) had leukocytosis at admission (a number of leukocytes> 10,000/µl). Thus, patients with leukocytosis were associated with Hartmann's interventions (p<0.01) (Table 1).

170 patients (39.44%) had hydro electrolytic disorders at admission (especially hypopotassemia). We considered that the patients with hydro electrolytic disorders were those whose ionograms on admission showed values of Na <136 mmol/l and potassium values <3.5 mmol/l. Patients with hydro electrolytic disorders were associated with a colostomy (p<0.03) (Table 1).

During the emergency surgery, in 13 cases (3.01%) the presence of peritoneal carcinomatosis was found (Figure 3). Peritoneal carcinomatosis has been associated with a colostomy (p<0.02). 81 (18.79%) patients had liver metastases, found either on preoperative ultrasound examination or the occasion of laparotomy (in most cases). Patients with liver metastases were associated with internal derivations (p<0.01) (Table 1).

Figure 3: Ascendant colon tumor, peritoneal carcinomatosis (II Surgery Clinic, Sf. Ap. Andrei Clinic Emergency County Hospital Galati)



45 (10.44%) of the patients had "frozen pelvis" (tumor block comprising other pelvic organs, to which there is firm adherence, with very difficult or non-existent cleavage planes, to which small bowel loops adhere). Patients with frozen pelvis were associated with a colostomy (p<0.01) (Table 1).

Regarding the location of tumors, 60 (13.92%) were located at the level of the ascendant and hepatic angle of the colon, 30 (6.98%) at the level of the transverse colon, 57 (13.22%) at the level of the descending and splenic angle of the colon, 133 (30.85%) in the sigmoid colon and recto-sigmoid junction and 151 (35.03%) were rectal tumors.

For the tumors of the ascending colon and hepatic angle, in most cases, resections with anastomosis (right hemicolectomies) were practiced, followed by internal derivations and cecostomies (p<0.01), the patients with tumors located on the descending colon and the splenic angle mainly benefited from internal derivations or Hartmann's interventions (p<0.01), for patients with tumor location in the rectum, colostomies were practiced (p<0.01) and for the transverse colon locations, resections with anastomosis (p<0.01) were performed (Table 1).

In 126 cases (29.23%) we encountered tumors invading other organs: 27 invasive tumors in the prostate, 26 cases with tumors that invaded the small intestine, 18 invasive tumors in the gastrocolic ligament/large epiploon, 13 in the vagina, 11 in the abdominal wall, 10 in the sacrum bone, 6 tumors were invasive in the bladder, 4 in the duodenum (+/- head of the pancreas) and spleen, 3 invasive tumors in the right/left annexes, 2 in the left renal capsule and 2 tumors that invaded the pelvic ureter. The subset of patients with invasive tumors in other organs was associated with internal derivations (p<0.01) (Table 1).

Data from the histological reports revealed the predominance of adenocarcinomas (99.76% of cases) and only one GIST tumor. 16 (3.71%) of the patients had tumors with a mucoid component.

Regarding tumor grading, 115 (26.68%) were well-differentiated adenocarcinomas (grade 1), 275 (63.8%) medium differentiated tumors (grade 2) and 41 (9.52%) weak tumors differentiate (grade 3). Well, and medium differentiated tumors were associated with colostomies or with resections with anastomosis (p<0.01).

For postoperative staging, we used the classification recommended by The Union for International Cancer Control (UICC). Thus, according to pTNM staging, tumors in stages II and III predominated - 106 (24.59%), tumors in stage II, 241 (55.91%) in stage III, and 84 (19.5%) in stage IV. The patients in stage II were associated with resections with anastomosis or Hartmann operations (p<0.01), patients with tumors in stage III were associated with colostomies (p<0.01), and patients in stage IV were associated with internal derivations and colostomies (p<0.01) (Table 1).

DISCUSSIONS

According to literature data, up to 30% of colorectal cancer patients present with complicated tumors in emergency [9]. Despite many standardization attempts, the best surgical option for patients with complicated colorectal tumors is still under debate. [5, 10]

We have shown in this study that the type of surgery in patients with complicated colorectal cancer correlates with: age, provenance area, associated cardiac diseases, history of the disease, cachexia at admission, oliguria and hydro electrolytic disorders, diagnosis, presence of liver metastases, and frozen pelvis appearance, tumor location, tumor invasion in other organs and staging.

There is no consensus regarding the surgical treatment of the elderly affected by colorectal cancer, but it is generally accepted that patients over 80, who present in an emergency, compared to the younger ones, have a higher risk of postoperative complications and mortality, despite the progress made in preoperative care, surgical techniques, and intensive care.[11] Most authors reported significant correlations between the type of intervention and the age of the patients [6, 12], as we found in our study, but different from the data obtained by other authors.[13]

Several authors found significant correlations between the type of operation and the patients coming from the rural area [14], as we found in our study. Most authors agree that patients in rural areas have lower addressability due to more difficult access to medical services and therefore tend to show up later, with more advanced tumors.[15, 16]

The comorbidities, especially the cardiac ones, are associated in many studies with the practice of non-curative interventions in patients with complicated colorectal cancer.[17, 18] We also found this correlation in our study.

The pathophysiology of cachexia syndrome is characterized by negative energy and protein balance. In neoplastic patients, it is a major cause of morbidity and mortality [19-22]. A recent study, which included 235 patients with advanced colorectal cancer, reaffirms the negative impact of cachexia on the evolution of the patients with complicated colorectal cancer.

Oliguria is considered a specific and sensitive biomarker of renal dysfunction and a good predictor of mortality risk in critically ill patients, including complicated colorectal tumors.[24, 25] For patients with complicated colorectal cancer, with oligoanuria at admission, colostomies are performed, according to several reports [26, 27], as we found in our study.

Neoplastic patients frequently present with hydroelectrolyte balance disorders. These occur during tumor growth, because of inadequate absorption of electrolytes or because of the secretion of metabolically active substances by the tumor [28]. The hydroelectrolyte disorders present at admission are associated with the type of surgery performed in patients with complicated colorectal cancer [29], as we have shown in our study.

The liver is the most common location of secondary dissemination of primary colorectal tumors. Between 10% and 25% of colorectal cancer patients have liver metastases at the time of surgery [30]. Despite all the therapeutic progress made in recent years, the presence of liver metastases remains a negative prognostic factor.[31] Most of the time, these patients have advanced tumors and the only viable option in an emergency is a colostomy, which will allow them to survive for several months.[32] We made the same finding in our study.

The type of surgery is associated with the preoperative diagnosis, which, most commonly, is the intestinal obstruction. The therapeutic attitude in these cases depends on the location of the primary tumor, the stage, the general state of the patient, and the local changes (tumor resectability, colic distention, ischemic lesions of the colic wall, integrity of the ileocecal valve).[33, 34]

For perforated tumors, Hartmann's intervention is the recommended option in most published works [35-37], as we have shown in our study. For hemorrhagic tumors, the options are different depending on the location of the tumor.

In our study, most hemorrhagic tumors were rectal, and the emergency surgical option was most often a colostomy, after a local bleeding control. In the literature, there is also mentioned the practice of arteriographic embolization in these situations [38], a technical possibility that we did not have.

Patients with locally advanced colorectal tumors, with invasion in other organs, can be a therapeutic challenge [39-41].In most cases, in these situations, a terminal colostomy is practiced [42], which also happened in our study group. Other authors have considered the practice of plurivisceral resections in these situations.

The first such series was reported by Sugarbaker in 1946.[43] Croner et al. performed a study on 174 patients who underwent plurivisceral resections during the period 1978-2002 [44]. Most of the patients had sigmoid colon cancers and the most commonly invaded organs were the small intestine, the bladder, and the abdominal wall.

The type of emergency surgery performed for complicated colorectal cancer is significantly statistically correlated with the colorectal tumor location in all the analyzed studies. Most authors consider, as in our study, that single-phase procedures for left colon tumors are not indicated in emergency and that in these situations the Hartmann procedure is preferable.[45, 46] But some authors believe that, including for occlusive left colon tumors, the first option should be a resection with anastomosis [7, 13, 47, 48]. For the complicated tumors located on the right colon, there seems to be unanimity regarding the surgical option, in these cases the right hemicolectomy being the option.[8, 49]

The TNM staging proposed by the AJCC has remained a universal model since its first edition in 1977 [50]. Since then, the guides have been revised several times and the last update was proposed in 2018 [51]. In our study, stage II of disease correlated with Hartmann's operation and stage IV with a colostomy, as we found in other works.[52, 53]

CONCLUSIONS

1) The colostomy was associated with: older age, rural area, associated cardiac diseases, especially atrial fibrillation, neglected symptomatology, cachexia, oliguria, anemia, and hydro electrolytic disorders at admission, tumors complicated with hemorrhage or with imminent diastatic perforation, the intraoperative aspect of the frozen pelvis, rectal tumors, well or medium differentiated tumors, advanced stages of disease (III or IV pTNM).

2) Hartmann's operations were associated with the significant hereditary-collateral history, neglected symptomatology, intestinal transit disorders and abdominal pain upon admission, leukocytosis, intestinal perforation, sigmoid, and recto-sigmoid junction tumors, and stage II TNM.

3) Internal derivations were associated with the presence of intestinal occlusion at admission, liver metastases, and invasion in other organs, with tumors of splenic angle or descending colon and with stage IV disease.

4) Resections with anastomosis per primam were associated with the absence of comorbidities, tumors located at the level of the ascendant colon, hepatic angle, or transverse colon and well-differentiated tumors.

Emerging concepts regarding the molecular profile of breast carcinoma: one-year experience in a University Center

Oana C. Voinea[1,2], Maria Sajin[1,2], Adrian V. Dumitru[1,2], Oana M. Pătrașcu[1,2], Tiberiu A. Georgescu[1,2], Monica M. Cîrstoiu[1,3], Dan C. Jinga[1,4], Adriana E. Nica[1,5]

Abstract: *Breast carcinoma represents the leading cause of oncologic mortality for women. Due to therapeutic and diagnostic advances, the mortality and morbidity in the last decade declined, but breast cancer still has a great impact on quality of life and also on medical service cost. In the light of these facts, an integrated approach, considering histopathology features, molecular profiles and corroboration with clinical and imagistic data is necessary. A descriptive retrospective one-year study analyzed the breast cancer heterogeneity in 121 cases registered in the Pathology Department of the University Emergency Hospital in Bucharest, Romania. Our purpose was to evaluate histopathological, immunohistochemically, clinical and imagistic aspects of breast cancer considering the current molecular classification (Luminal A, Luminal B, HER2 enriched and triple negative/basal like).*

Our assay revealed that most prevalent histotype was NST (no special type) followed by invasive lobular carcinoma. Considering the molecular pattern, the most common was luminal B. Triple negative basal like and HER 2-enriched were correlated with an aggressive morphologic pattern and lymph-nodes positivity. Considering the imagistic acquisitions, mammography proved to be the most accurate technique for measuring the dimension of NST.

In conclusion, breast carcinoma is a heterogeneous disease that needs an integrated approach and personalized treatment based on the histopathologic and molecular features. Considering the great number of advanced stages as diagnosis, a national screening program for breast cancer is imperiously needed.

Keywords: *breast cancer, NST, ILC, IHC, molecular subtypes, biopsy*

INTRODUCTION

According to the most recent statistic database of WHO 2015, breast carcinoma represents the main cause of mortality for Romanian women [1]. The decline of breast cancer mortality is a trend that, according to the most recent epidemiologic estimation will continue [2]. This direction is mostly due to advancement in diagnosis and treatment [3].

A better understanding of pathogeny and a more accurate diagnostic approach of breast cancer led to several updates in guidelines for classification and treatment. Since 2003, for grading breast carcinomas, the Elston Ellis semiquantitative method modified score was used according to the 3rd edition of WHO guidelines for classification the breast tumours. The most recent WHO diagnos-

[5] Department of Anesthesiology and Intensive Therapy of University Emergency Hospital, Bucharest

tic guideline (4th edition, 2014) considers that for prognostic and predictive factors a panel of antibodies is needed for a further classification into molecular subtypes (luminal A, luminal B, Her2 enriched and triple negative basal-like). This approach is supported by multiple studies and summarized in the most important European or American conferences or guidelines. For example, the 14th St. Gallen International Breast Cancer Conference, 2015 [4], considers breast carcinoma a heterogeneous pathology according to its intrinsic molecular types whereas the 8th edition of AJCC (American Joint Committee on Cancer) states that breast malignant tumours should be staged according to the prognostic group, based on population that had been offered and mostly treated with appropriate endocrine or systemic therapy which includes anatomic T, N and M plus grade and status of HER2, ER, PR. [5]

MATERIAL AND METHOD

The aim of this retrospective analysis was to offer an exhaustive perspective of breast cancer considering clinical and imagistic presentation, morphological and molecular profiles of the main mortality factor for women. We analyzed the breast cancer heterogeneity in 121 cases registered as mastectomies, lumpectomies, quadrantectomies or biopsies in the Pathology Department of the University Emergency Hospital in Bucharest, performed over a period of 1 year (1st January 2017-31st of December 2017). The diagnostic varied from benign lesions (fibroadenoma, fibroadenomatoid mastopathy) to the most common malignancies, NST carcinoma and even rare cases like carcinoma with medullary features, mucinous, adenosquamous, papillary carcinoma or Phyllodes tumor.

For clinical data and imagistic interpretation, we used the hospital electronic database. The histologic specimens were studied using both conventional histopathological examination with HE stains and also immunohistochemically methods, classifying them further in the main 4 surrogate-molecular subtypes: luminal A, luminal B, HER2-neu non-luminal and basal-like/triple-negative. For diagnosing the main histologic subtypes, the last WHO guideline criteria were applied. For data collection and processing Microsoft Office Excel 2010 was used.

Table 1. Frequency of the surgical procedures used for the histopathological diagnoses in the analyzed population

Type of lesion	Mastectomy + axillary in dissection	Lumpectomy	Core needle biopsy	Total
NST	40	19	19	78
NST with papillary features		1		1
Invasive lobular carcinoma	4	1	3	8
Medullary carcinoma	1			1
Adenosquamous carcinoma	1			1
Phyllodes tumour	1			1
Adenomioepithelioma		1		1
Metastasis of B cell lymphoma		1		1
Benign lesions, non-inflammatory	5	5	1	11
Fibroadenomas	1	8	2	11
Benign lesions, inflammatory	1	3		4
Metastasis of breast carcinoma			3	3
Total	54	39	28	121

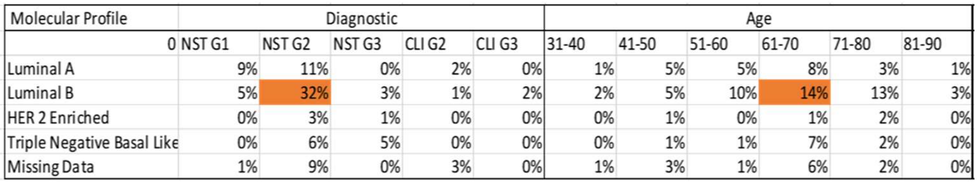
RESULTS

This one-year retrospective study analyzed 121 cases female patients registered in Pathology Department of the University Emergency Hospital in Bucharest with diagnostic of benign lesions and also with malignant pathologies. Those included carcinomas, with NST histotype being the most common (78 cases), ILC (8 cases) and also rare types. Detailed information is found in Table 1.

We focused our attention on the most common types of breast carcinoma: NST and ILC. In our study the most common histotype of breast carcinoma was NST, with a predominance of G2 grade of differentiation (59%), followed by an equal percentage of G1 and G3 (8% for each one).

In the absence of precise data about menstrual status, we considering the climax age at 50 years old. With this presumption, most women were postmenopausal (79%), and the average age at presentation was 61.48 years, varying from 35 to 86 years old. Distribution of the analyzed patients according to their age, histotype and molecular profile of their tumor is detailed in Table 2.

Table 2. Age distribution according to the main histotype, grade of differentiation and molecular profile of the most important histotypes of breast carcinoma



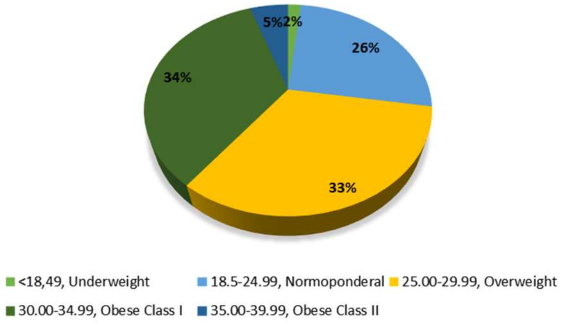
Molecular Profile	Diagnostic					Age					
0	NST G1	NST G2	NST G3	CLI G2	CLI G3	31-40	41-50	51-60	61-70	71-80	81-90
Luminal A	9%	11%	0%	2%	0%	1%	5%	5%	8%	3%	1%
Luminal B	5%	32%	3%	1%	2%	2%	5%	10%	14%	13%	3%
HER 2 Enriched	0%	3%	1%	0%	0%	0%	1%	0%	1%	2%	0%
Triple Negative Basal Like	0%	6%	5%	0%	0%	0%	1%	1%	7%	2%	0%
Missing Data	1%	9%	0%	3%	0%	1%	3%	1%	6%	2%	0%

Most patients addressed to surgery or Obstetrics-Gynecology Departments of the University Emergency Hospital in Bucharest for painless tumor masses. We also noticed sporadic cases of ulcerated bleeding tumors. A single patient presented for asymptomatic tumor incidental discovered with mammographic screening.

A demographic brief analysis revealed that most patient came from urban areas, with a percentage of 56% for the latter and 44% for rural areas; taking a closer look, we observed that the majority of advanced stages (III and IV) were more frequent in women with urban provenience (10.7% for stage III respective 4.7% for stage IV) in comparison to rural population that addressed to our hospital (1.2% stage III and 0.6% for stage IV).

Regarding clinical data obtained from hospital database, we noticed that the metabolic profile of a majority of analyzed women was impaired, most of them being overweight and obese, only a quarter bearing a normal weight, as the Figure 1 reveals. More than half of studied patients suffered dyslipidemia and experienced cardiovascular complications (essential hypertension and atherosclerosis were most noted). A subgroup also registered a history of gynecologic or endocrine pathology but not enough for a trustable correlation.

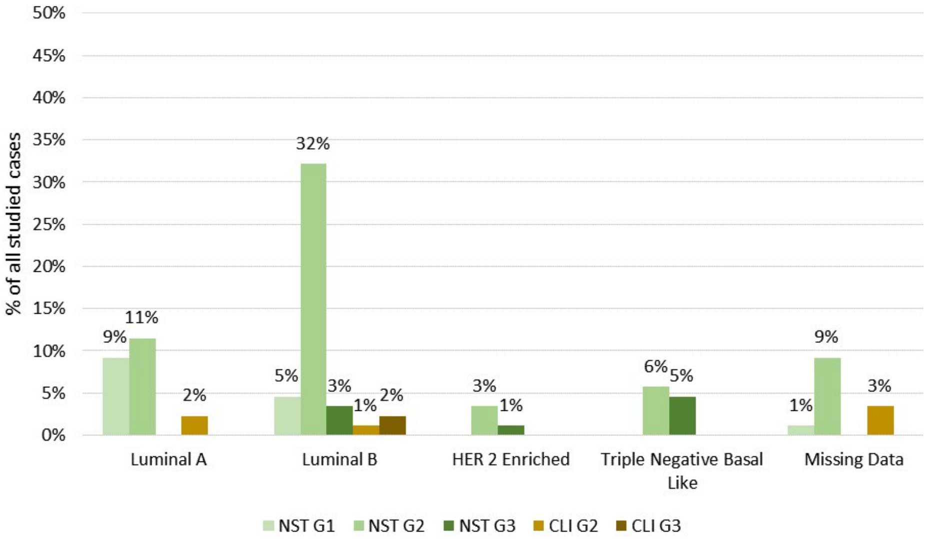
Figure 1. BMI of analyzed cases



When we put side by side the matric data of different types of investigations (ultrasonography, mammography at CT) with histopathological measurement (macroscopically and microscopically evaluation) we noticed that the highest accuracy in appreciating the dimension of breast lesions is radiologic examination (mammography and CT), followed by ultrasonography which tend to underestimate most of lesions. Considering the main histotypes, the most difficult breast tumor to be precisely measured in conventional imagistic methods is invasive lobular carcinoma, in accordance with its manner of infiltrating the mammary tissue.

With the available data, we observed that invasive breast carcinomas were all scored with BIRADS 5 or 6, a single case of NST G1, luminal A, T1c being underappreciated as 3.

Figure 2. Molecular profile of breast carcinoma according to histotype (%)



In relation to histologic examination of breast cancer, formalin fixed-paraffin-embedded tissue were studied using both conventional histopathological examination including HE stains and also immunohistochemically methods, classifying them further in the 4 main surrogate-molecular subtypes: luminal A, luminal B, HER2-neu non-luminal and basal-like/triple-negative. For diagnosing the main histologic subtypes, the last WHO guideline criteria were used.

When we evaluated breast cancer histotypes and their molecular pattern, we observed that the most prevalent is luminal B with a pick incidence in NST grade 2, followed by luminal A, also most prevalent for NST G2.

The oncologic stage according to WHO 2014 for HER 2 enriched and triple negative varied between IIB and IV. We did not find any single case in stage I. We also observed that for luminal A category the majority of cancer were in stage I and II. An interesting aspect is registered for luminal B, the most frequent molecular type of our statistic. We can easily observe that it has the highest frequency in most of cases, but not in stage I of disease. A more explicative illustration of the preponderance of tumor stages according to the 7th edition of UICC for TNM classification of malignant tumors, in relation to their molecular profile is highlighted in figure 3.

Figure 3. Molecular profiles of tumor stages related to the molecular profile

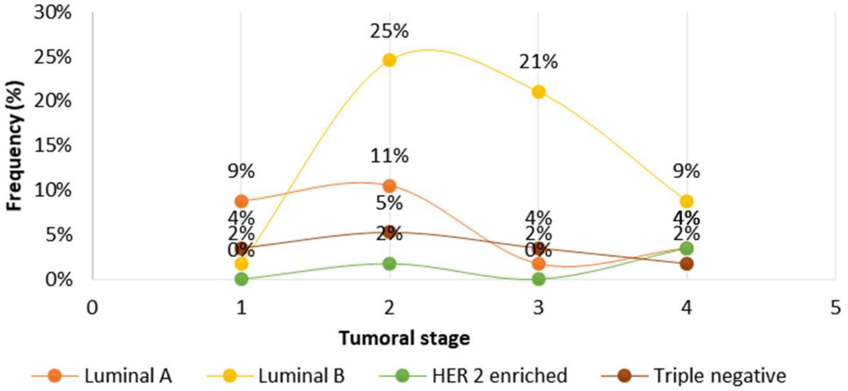


Figure 4. Regression between ER expression and KI 67 in luminal A and luminal B breast carcinomas

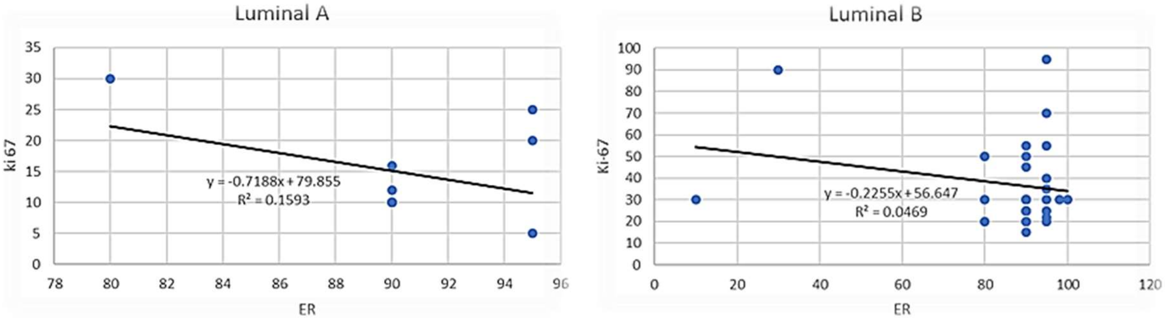


Considering the hormonal expression in the luminal type carcinomas and their proliferation index, we observed the regression between ER expression and the mitotic index evaluated by Ki 67 in luminal molecular profiles. For luminal A there is a better correlation between a higher expression of ER and a lower Ki 67 (R2=0.159) comparing to luminal B (R2=0.046), as in the Figure 4 can be easily seen. The juxtapose of the two types was not only useful for understanding the variation of hormonal variation regarding the proliferation rate, but also necessary considering the limited number of analyzed cases.

In our study, no invasive lobular breast carcinoma was identified among non-luminal carcinomas. We registered more triple negative than HER 2 enriched molecular subtype, and their prevalence were highest in climax women. As expected, their histologic features were more aggressive, with large areas of necrosis, infiltrative pattern of growth, and large numbers of mitoses, none of those being graded as well differentiated.

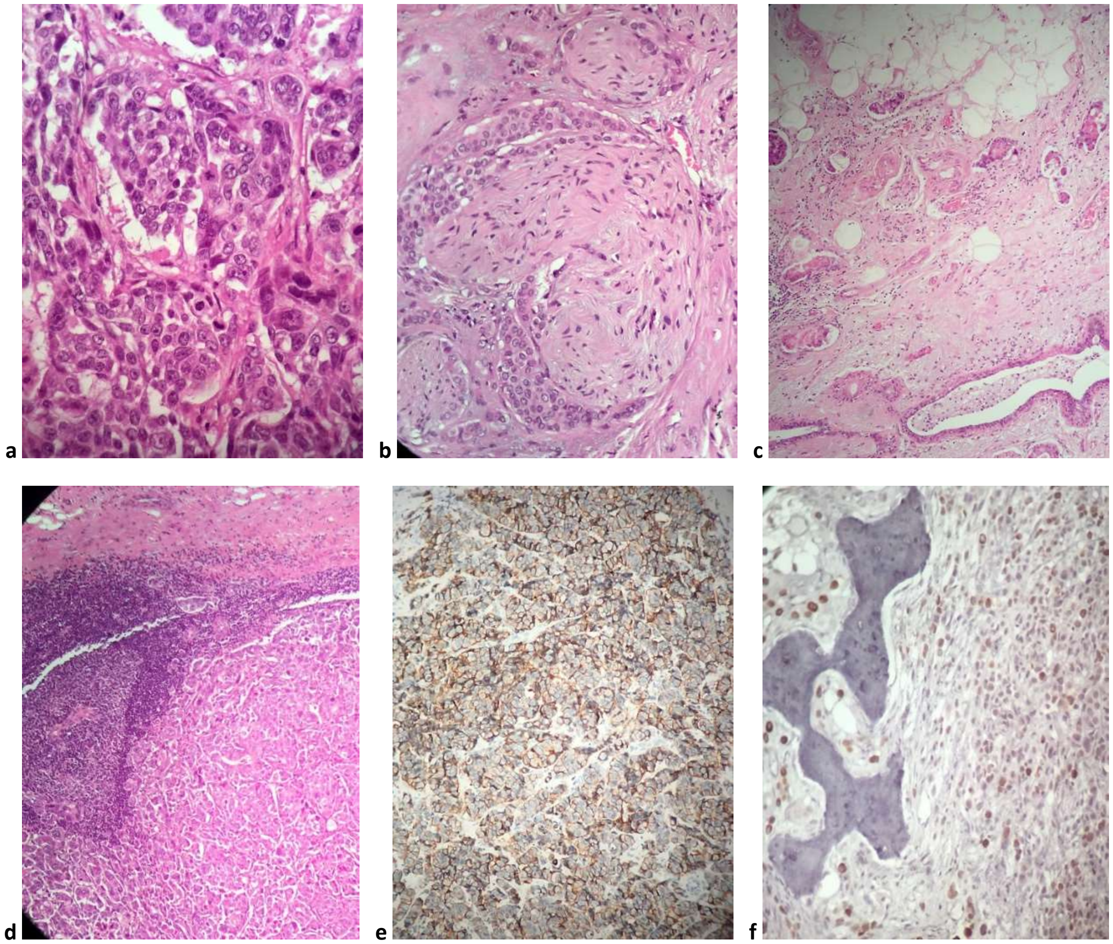
DISCUSSION

Breast carcinoma is not a single disease, it has a large panel of shapes, clinical manifestations, imagistic and histologic representations. The current WHO guidelines for breast carcinoma counts 37 different coded histotypes, but this classification it is far from being adequate for proper treatment [6]. Tumors with identical clinical and pathological presentations may have different behaviors. Beside the TNM classification and grading method (today the Nottingham histologic score system is universally accepted), the interest for treating in the most efficient and precise way each particular biological form of disease gave birth to the molecular subtype classification. This procedure evaluates the hormonal expression of tumor tissue (ER, PR), presence or absence of HER2 protein and levels of Ki-67.

We started our analysis by looking on the preferred diagnostic procedure, and in some cases, it was similar with the surgical treatment. The method of choice for the majority of invasive breast carcinoma clinically diagnosed is represented by mastectomies with axillary lymph node dissections were. Most of these procedures started with a frozen section for certifying the malignant nature of the lesion. After the frozen section, surgical interventions ended with mastectomy and lymph node dissection. Less than half of analyzed women received a neoadjuvant chemo-radio-therapy after core needle biopsy and came back for completing the surgical treatment.

The concordance of core needle biopsy and surgical excision specimen for diagnosing the histotype and hormonal profile of the tumor was proofed to be safe in large studies [7, 8]. According to ESMO, assessment of primary tumor includes: physical examination, mammography, breast ultrasound for lymph node determination, breast MRI and core biopsy with pathology determination of histotype, grade, ER, PR, HER-2 and Ki67 status. If preoperative systemic therapy is planned, a core needle biopsy is mandatory to ensure a diagnosis of invasive disease and assess biomarkers (recommendation IIIA) [9].

Figure 5. NST HER2 enriched carcinoma a. Numerous atypical mitosis HE 40X; b. perineural invasion, HE 40X; c. Intravascular tumor emboli; d. Lymph node invasion, HE 10X; e. HER2 intensely positive, scored 3+, 20X; HER2 negative, score 0, 20X.; f. Bone metastases with GATA 3 positivity suggesting breast origin, 20X.



Since it is not yet a standardized method, CNB does not represent a IA indication for non-operative diagnostic. Even if the Royal College of Pathology [10], the WHO guidelines for breast cancer and AJCC 8th edition [5] enclose certain recommendation for reporting the results of a CNB, this practice is controversial regarding the rate of metastasis [11], the reliability of histological grade considering the dimensions of collected fragments [12], the limitation in diagnosing certain subtypes of carcinoma (e.g. mucinous carcinoma) [13], and even rise the problem of “vanishing carcinoma”, when tumor cells are present on CNB but absent in the surgical specimen [14];

We focused our attention on the most frequent histotypes of breast tumors, NST and ILC. The rare types of malignancies like papillary carcinoma, medullary carcinoma, Phyllodes tumor or metastasis to the breast are not well represented in this one-year study and for the sake of statistic relevance, we choose not to include them in our calculation. Also, the benign lesions (fibroadenoma, adenomyoepithelioma, abscesses or fibrocystic disease) were not relevant for the heterogeneity of breast carcinoma.

The interesting demographic results that we obtained underlines that the majority of severe stages of disease (stage III and IV) were addressed from urban population. This trend is not observed in other studies made in Australia [15], Africa [16] or even in multiethnic and multiracial population [17], but in our opinion, these unexpected results may appear because of many reasons: probably the most important one is the limited number of cases that were included in our analysis. Other reasons may consider the higher addressability of urban women to private health system, the migration of urban population to the country side or a better surveillance of patients from rural area by their family doctor. On a deeper assessment, it is easily noticed that most of our luminal B cases had a high Ki 67 index (above 20%), only a third of them being HER2 positive or equivoque on IHC. A possible explanation could be the absence of a -ISH method in our department for a precise assessment of HER 2 mutation. Anyway, considering the limited period and number of analyzed cases, for a more accurate distribution of luminal subtypes more studies are needed.

Taking into account hormonal expression, using regressions, we observed that for luminal A molecular subtype the higher the estrogen receptor expression is, the lower the proliferation index is (quantified by Ki 67); in comparison, for luminal B subtype p-value was only 0.0469.

Regarding the age, the highest amount of breast cancers appeared in the 6th decade of life, with a considerable delimitation between pre- and post-menopausal age. Even so, in the 3rd decade we registered only luminal subtypes of cancer (considered to have a better prognosis) but in the 4th decade we registered all the molecular subtypes.

Regarding clinical correlation, we became aware of the impaired weight of our studied group, most patients being overweight, with a medium BMI of 27.73. Also, we noticed that a great proportion of studied women who underwent a diagnostic biopsy and returned after approximately 3 months for surgical treatment gained extra kg, their BMI being augmented. This observation could be an alarm signal for a better nutritional surveillance and psychologic management of oncologic patients, considering that obesity it is an important risk factor for malignancy, comorbidities and mortality [18 - 20].

Unfortunately, our clinical correlation was limited because we did not had access to variables like family and history of menstruation, oral contraceptive use, age of first full-term pregnancy, number of children, duration of lactation or hormonal replacement therapy.

CONCLUSIONS

In our study, primary malignant epithelial tumors of the breast were NST with a moderate grade of differentiation with an age of incidence ranging from 3rd to 8th decade, being most prevalent in the 6th decade. Regarding molecular classification, luminal B was more common than others, with a wide clinical and histologic appearance; it was found in all analyzed histotypes and in all pathologic stages of disease. Because of its predominance, most of severe cases we registered (metastatic breast disease, ulcerated tumors) were also luminal B subtype. We admit the limitations of our study (few cases in a single year in a single hospital with emergency profile) but we are convinced that for a better breast cancer management, keeping in mind the most important aim, a lower mortality and morbidity, a proper national screening program is of an imperative necessity.

Endoscopic treatment in carpal tunnel syndrome

Hazim Elayan[1], Jawad Latif[1], Ana M. Oproiu[2], Radu C. Jecan[2], Ioan P. Florescu[2]

Abstract: *Carpal tunnel syndrome is currently the most common peripheral nerve compression neuropathy that affects approximately 1% of the population [7,8,9]. The incidence of CTS seems to be increasing. The diagnosis is based on clinical symptoms and electrodiagnostic studies.*

Keywords: *endoscopic, carpal tunnel, median nerve, compression*

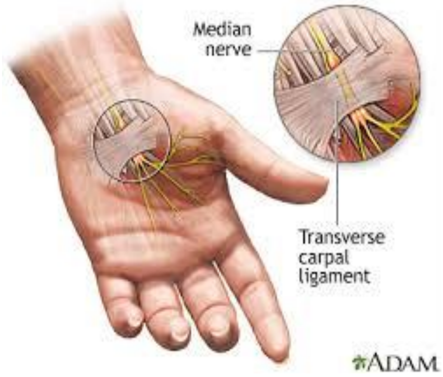
INTRODUCTION

Definition

Carpal tunnel syndrome is the compression of the median nerve in the wrist (radiocarpal joint and palm) and the most common neuropathy in the upper limb. Paresthesias, especially nocturnal pain, numbness and weakness of the hand, tingling, atrophy of the thenar muscles are the most common clinical signs of CTS in addition to the Tinel sign, the Phalen and Durkan test, ultimately leading to severe damage to the hand and forearm [1].

Anatomy

The Carpal tunnel consists of the carpal bones and the transverse carpal ligament that forms the roof of the tunnel and extends from the hamat bone (hook bone) and triquetrium (pyramidal bone) on the ulnar side to the scaphoid and trapezium on the radial side. The carpal bones are located in 2 rows (from radial to ulnar); proximal row: scaphoid, lunate, triquetrium, and pisiform bone, distal row: trapezium, trapezoid, capitate, and hamat. Through this canal pass the median nerve which is accompanied by the artery of the median nerve wrapped in a "perinerv" sheath and the flexor tendons which are wrapped by the synovial sheath which helps the proper functioning of the flexor apparatus under normal conditions. (long thumb flexor, four superficial flexors of the fingers, and four deep flexors of the fingers).



Also at the wrist, there is a canal where the ulnar vascular-nervous package passes called the Guyon canal, which may or may not be affected at the same time as the carpal tunnel syndrome.

Etiology

Among the causes of CTS are: idiopathic, hereditary,

Diagnostic

It is put in principle on the clinical signs, the Tinel sign, the Phalen and Durkan test, then it is passed to the paraclinical analyzes: electromyography (EMG), nerve conduction speed, radiology, ultrasound, MRI, laboratory blood tests.

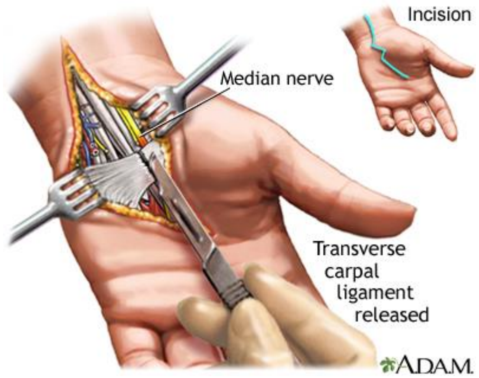
The costoclavicular Adson and Wright tests are used to exclude chest compression syndrome that can mimic CTS. Cervical examination, including the Spurling test, is essential to exclude cervical radiculopathy. The percussion of all the primary peripheral nerves can lead us to an unexpected area of compression [2].

A study of nerve conduction speed and electromyography is performed. They help us to confirm the diagnosis of CTS and to exclude other patho-logy[3].

Basic x-rays of the wrist are useful in detecting unexpected pathology.

TREATMENT

Over time, several treatment methods have been tried; conservative by rest and immobilization, treatment with topical or infiltrated anti-inflammatory drugs in the carpal tunnel (in rare cases), and surgical treatment by a classical or endoscopic technique that have proven effective compared to conservative treatment which is considered a way of delaying surgery; Surgical treatment by classical technique involves a curved longitudinal incision parallel to the tenerian crease for prolonged sometimes proximal zigzag to forearm through the flexion creases of the wrist to relax the forearm fascia, external or internal neurolysis, sinevoectomy or remove any formations that can compress the median nerve, sectioning TCL from proximal to distal on the ulnar side to avoid injury to the thenar motor branch, hemostasis control, skin suture, dressing, and immobilization. Risks including pillar pain, weakness in the hand, sensitivity to scarring, delayed return work and slower return to office, relatively long recovery period, and the risk of adhesions. This technique has proven good over time, but because medicine is evaluating and we are continuing our search for new techniques and procedures to minimize risk and recovery time, we will present endoscopic surgical treatment.



History of carpal tunnel endoscopy

Interest in less invasive open procedures for treating CTS developed in the early 1980s. Paine [4], a neurosurgeon, used a retinaculatom to divide TCL through a small transverse incision in one of the creases of the wrist. However, he found a 2.5% incidence of the incomplete division of the TCL. There were four cases of palmar hematoma, most likely developed due to superficial palmar arch injury. Pagnanelli [5] reported the use of retinaculatom in 577 patients and had only two incomplete divisions (0.3%) of TCL with no median or vascular nerve injuries.

In the history of carpal tunnel endoscopy, 2 main techniques for relaxing the carpal tunnel have been described; "One portal procedure" and "duel portal procedure". The first endoscopic technique was introduced in the relaxation of the carpal tunnel "one portal procedure" in 1986-1987 by Okutsu, a Japanese orthopedist, and in 1989 the technique

"Duel portal procedure" was introduced by Chow, an orthopedist. the two techniques had modifications and developments by other doctors (Agee, Menon, Worseg, Brown, Tsai Resnik, and Miller...) but remained in 2 categories: one portal procedure and duel portal procedure.

Indications

The indications are similar to those of classical technique and include the severity of symptoms, duration of symptoms, ineffective response to conservative treatment.

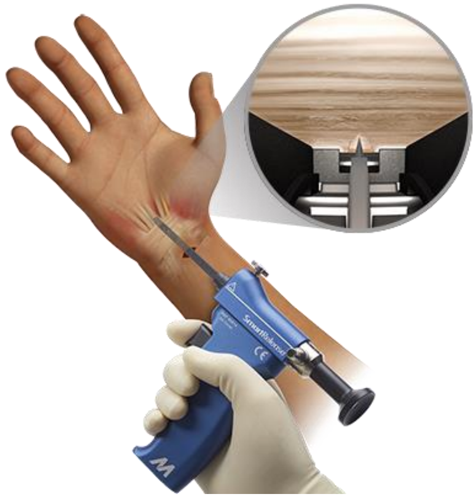
Relative contraindications

Include patients with severe CTS with evidence of muscle atrophy, rheumatoid arthritis, previous surgical treatment of repeated CTS !!, significant loss of wrist extension, proliferative synovitis, and lesions invading the carpal tunnel [2].

Endoscopic surgical technique

One portal procedure (Agee's technique modified):

Following the inflation of a tourniquet with the initial recommendation of general or regional anesthesia, then with the evolution of the surgeons' experience, they started to use local anesthesia with or without sedation, a 2-3 cm incision is made in one of the flexion creases of the wrist between ulnar carpal flexor and radial carpal flexor. Longitudinal subcutaneous dissection exposes the forearm fascia.



A U-shaped incision is made on the forearm fascia, creating a rectangular flap based distally on the TCL. While the flap is raised, a synovial lift is placed under the TCL [6]. An instrument (a kind of dilator) is inserted into the carpal tunnel to create a path for the blade assembly. The blade endoscope assembly is then inserted into the carpal tunnel and is passed distally to the distal edge of the TCL. A few steps are usually required to obtain an adequate definition of TCL. After defining the distal edge of the ligament, the tip of the instrument (along with the blade) is placed distal to the edge of the TCL. After checking the correct positioning, the trigger mechanism is activated and the blade is engaged and raised to 3.5 mm above the assembly at an angle of 80° [6]. The instrument is retracted, and under direct view, the TCL is split in a distal to proximal direction. With the blade retracted, several passes can be made to check the ligament transection. If necessary, the blade can be coupled and the remaining TCLs can be sectioned. Then, a proximal volar antebrachial fasciotomy is performed, followed by standard closure of the wound.

Dual portal procedure (Chow's technique and its modifications):

His original technique involved a transbursaral approach to the carpal tunnel. The surgeon and the nurse should sit in front of each other at the hand table. A TV monitor is placed behind each surgeon so that both can have a complete view of the procedure. A transverse incision of 1 cm is made at 0.25 cm proximal and 0.25 cm radially from the pisiform bone. Chow later modified his technique by changing the landmarks of the proximal incision [3, 7, 8]. He recommended that the proximal portal be made by drawing a transverse line of 1 to 1.5 cm radially from the proximal pole of the pisiform bone. A second line is longitudinally marked 0.5 cm from the end of the first line. A third line is transverse 1 cm to the radial from the end of the second line to indicate the entrance portal. A longitudinal incision is made on the forearm fascia, taking care to protect the artery and the ulnar nerve. The flexor tendons are exposed (trans-bursal) and retracted towards the radial part, finding the space between the ulnar neurovascular bundle and the flexor tendons. A trocar is inserted, and the wrist is placed and held in hyperextension by a special hand frame. Using the tip of the trocar, feel the base of the harness hook, then lift it and feel it, if you feel the cannula means it is above the TCL or in the Guyon channel and must be removed and reinserted into the channel under the TCL. A second incision (the palmar one) is made is distal to the distal edge of the carpal transverse ligament along the long axis of the ring finger. The endoscope is inserted proximally into the trocar, which has an end that is immediately below the TCL. Steps are taken to ensure that only the transverse fibers that makeup TCL are visible and not tendons or nerves. The endoscope is inserted into the proximal incision and advanced to the distal edge of the TCL. A knife inserted through the second incision (palmar incision) is used to cut the distal edge in a proximal direction up to half the ligament. To complete the release of the TCL, the endoscope is inserted into the distal opening. The knife is used to cut the proximal edge of the TCL, and the retrograde knife is inserted into the middle section and advanced proximally to complete the release. The wounds are sutured, a simple dressing is applied, and the sutures are removed after one week postoperatively. Because the transbursive technique frequently produced ulnar neuropaxia, either due to withdrawal pressure or the cannula, the technique was modified by Resnick and Miller [9] in a subligamental or extracurricular approach. In this technique, the forearm fascia is incised proximal to the TCL, and the dissection is made under the fascia and in the carpal tunnel under the ligament, avoiding the flexor tendon bursa. The rest of the operation is performed in a similar way to the Chow method.

In our clinic, we use the endoscopic technique "one portal procedure” (Figures 1 to 6).

COMPLICATIONS

Endoscopic carpal tunnel release-specific adverse events have been described and are listed here to avoid these possible complications.

1. Nerve injury:

This usually involves the digital nerve of the middle and/or ring finger, which are in a straight line coinciding with the insertion of the endoscope [10, 11, 12].

2. Lesion of the superficial palmar arch:

Because the distance between the superficial palmar arch and the distal edge of the transverse carpal ligament is approximately 9.4±3.5 mm [11, 13], insertion of the endoscope too distally should be avoided.

3. Flexor tendon injury:

This is due to an absence of experience using the endoscope and most commonly affects the superficial flexor tendon of the ring finger, typically a risk in the one-portal procedure [11, 12].

4. Penetration of the Guyon Canal:

This can injury the nerve or the ulnar artery [11].

5. Incomplete sectioning of the TCL

The only recognition of this may be the persistence of carpal tunnel syndrome symptoms in the postoperative period [11].

Benefits (advantages)

Minor postoperative pain, faster recovery, no immobilization of the hand, minimal scarring, faster return to work.

Disadvantages

Higher cost. inability to excise the formation or other structures that may compress the median nerve.

CONCLUSIONS

1.It is a modern technique that requires a special professional experience of the surgeon.

2.It is a minimally invasive technique with the protection of noble elements (vessels, nerves, and tendons) at this level (from the radiocarpal joint and palmar).

3.Recovery of the hand-operated much faster with endoscopic technique (does not require immobilization, rapid socio-professional reintegration).

4.The duration of surgery in an experienced surgeon is much shorter than with the classical technique.

Evaluating the effects of medication reconciliation by pharmacists on patient safety in hospitalized patients

Fatemeh Izadpanah[1], Mandana Moradi[2], Mina Amini[3], Amirsia Rahimpour[4]

Abstract: *Backgrounds: Medication errors are one of the most common errors that are associated with adverse effects on patients and may even lead to mortality. One of the methods for determining patient safety in hospitals is assessing the prevalence of medication errors. In this regard, medication reconciliation is used to improve drug safety in the treatment process. The present study was conducted on 7564 patients in the emergency department of one of the hospitals in Tehran, Iran.*

Methods: In total, 256 adult patients with a mean of 45 years, who had been admitted to the emergency department of a hospital in the past six months and had used at least three drugs before admission, were entered into the study. In this study, the effect of medication reconciliation on admitted patients was assessed to prevent drug errors at the time of admission by pharmacists. The main outcome measure was Type and Frequency Percentage of Drug Differences Observed during Medication Reconciliation were measured.

Results: According to the results, the presence of a trained pharmacist was significantly effective in medication reconciliation for enhancing patient safety and treatment process accuracy. In addition, it was concluded that age, the condition of hospitalization, and medical center personnel had a direct relationship with the frequency of medication discrepancies.

Conclusion: The presence of a trained pharmacist to perform the medication reconciliation process significantly affected the improvement of patient safety and the accuracy of the treatment process.

Keywords: *medication reconciliation; pharmacists; patient safety*

INTRODUCTION

Medication errors are quite prevalent and are the fourth leading cause of death all over the world. These errors may occur through dug prescription, preparation, distribution, or administration [1, 2, 3]. Some patients like the elderly, are at higher risk of medication errors because they always suffer from different comorbidities and use complex drug regimens [4]. A study in one of our teaching hospitals indicated the high rate of medication errors especially the missed dose errors [5]. It is one of the most important goals of all health care systems to prevent different types of medication errors.

The medication reconciliation process is a method to identify the most accurate list of all medications a patient is taking, to improve patient safety. It is always performed on

admission, to compare patient drug history with what is ordered in the hospital, and discharge as well as transferring from one ward to another [6]. It was first incorporated as a National Patient Safety Goal (NPSG) in 2005 by the Joint Commission. WHO and collaborators have designed a project for its implementation in a range of countries [7]. This process can effectively reduce the rate of different types of medication errors in hospitals [8, 9, 10]. It can also decrease the rate of readmission and its related costs [10].

Medication reconciliation is known as an important tool to prevent drug-related problems and their related burden. This process includes four stages, as follows:

- Preparing and recording the medication history of patients upon admission
- Comparing the medication history of patients with drug orders in the hospital and identifying and resolving discrepancies
- Providing a written list of medications upon the discharge of patients
- Teaching drug regimens to patients upon discharge [11].

Evaluating the medication reconciliation process supports the role of pharmacists as key members dealing with patients' medications, and collaboration between pharmacists and other healthcare team members is crucial in preventing drug-related errors and promoting patient safety especially in high-risk patients [12]. Medication reconciliation is a difficult and time-consuming process and is affected by factors like drug resources, the discharge process, and hospital policies. Distinguishing different barriers will contribute to the improvement of the exact drug information available between different health care settings [13].

Considering the impact of the medication reconciliation process on patient safety and the fact that this process used to be managed by doctors, medical interns, or nurses in our hospitals and is recently reformed with emphasis on the role of pharmacists, we designed this study to evaluate the following objectives in one of the hospitals in Tehran:

- Determining the difference between drug history taken by pharmacists and nurses
- Determining the frequency of identified errors in the reconciliation process
- Determining the frequency of identified errors related to dangerous medications (high risk)
- Determining the time spent for each medication reconciliation (time of comparison of BPMH and the current medication prescription inserted into the patients' file by the physician), resources used for history taking, the mean amount of medications used before admission, and time spent for corrective measures.

Ethics Approval

This study was approved by the Guilan University of Medical Sciences Ethics Committee.

MATERIALS AND METHODS

The impact of admission medication reconciliation by pharmacists on the rate of medication errors was assessed in this study.

During the six months from September 2019 to March 2019, 256 patients who were admitted to the emergency department of one of the general private hospitals in Tehran, were included in this study. The hospital had 350 approved beds and 300 active beds with an admission rate of 50 % in the emergency ward.

Inclusion criteria:

- Age over 45 years old,
- History of taking at least 3 medications at home

Medication reconciliation was conducted by trained hospital pharmacists from 8 a.m. to 8 p.m. each day. Patients who were admitted after 8 pm were visited by pharmacists the following day.

During the study period, all patients who were admitted to the emergency department were referred to the pharmacist for medication reconciliation if met the inclusion criteria. The pharmacist collected the best medication history (BPMH) from the patients or their caregivers as well as other information sources like patient GP or local pharmacy if required, using effective communication skills. Information sources were specified in medication reconciliation forms (MRFs). Insurance company records were also used to determine the details about drugs that were covered by insurance. Patients were also asked to bring all the medications they were using at home, if there were any, to provide more details. All the following information were entered in medication reconciliation forms:

- History of chronic diseases (e.g., diabetes, hypertension, hyperlipidemia, metabolic and genetic disorders, seizure, history of myocardial infarction (MI), and stroke)
- Any weight loss or weight gain diet and related medications
- Any herbal drugs in the form of topical, tea, and distillates

- Any prescribed and non-prescribed drugs
- Any high-risk medication as an anticoagulant, chemotherapy, antic arrhythmia, anti-convulsion, immunosuppressant, insulin
- Generic and brand name, dosage, frequency, and route of administration as well as how long days were on that medication were specified about each medication.
- History of smoking, alcohol, and narcotics
- Pregnancy and breastfeeding status
- History of any drug and food allergy

Then MRFs were compared with the medication history recorded in patient's files who were routinely taken by nurses. It was also compared with doctor's drug orders on admission. Any differences observed at this stage that required correcting the doctor's order were considered as clinical interventions.

The time spent by pharmacists and nurses to provide the BPMH were also recorded for each patient,

Finally the following were evaluated

- The differences between medication histories taken by the pharmacists and nurses
- The frequency of medication errors during the reconciliation process
- The frequency of medication errors related to high-risk drugs
- The time spent on each medication reconciliation
- Information sources used to take the medication histories and an average number of medications used before admission.

RESULTS

About 46% of our study population were male and 54% were female with a mean age of 61 (±16) years, they were taking 3- 10 medications before hospital admission (average of 6 drugs). Our results showed that from 256 patients who entered the study, 92 patients required some kind of clinical intervention. These interventions were approved by medical doctors in 87 cases, that 15.2% of these interventions were related to high-risk drugs.

In addition, we observed at least one difference between MRFs and medication history by nurses in 98.7% of cases. (1025 cases) which 13.4 % of these differences were related to high-risk drugs. Details about these differences are described in Table 1. Drug omission was the most prevalent difference we observed in this study. The second and third most prevalent differences were about dose and frequency of drug administration.

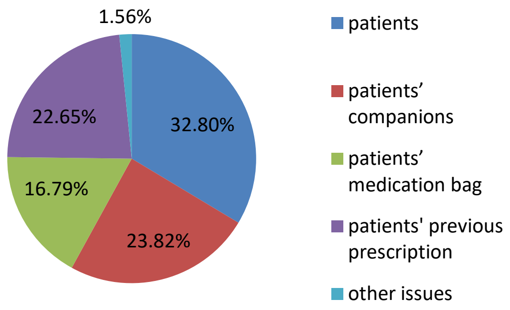
Table 1: Type and Frequency of differences Observed between MRFs and nurses medication histories

Type of observed medication error	Frequency percentage of error
Drug omission	48%
Dose	21%
Drug regimen	20%
Drug name	5%
Drug duplication	3%
Dosage form	2%
Other cases	1%

Regarding the time spent taking BPMH, we observed that pharmacists spent an average of half an hour to feel an MRF compare to 3 minutes, for taking a medication history, by nurses. In addition, the average time spent on comparing MRFs with doctors' drug orders was 12 minutes and it took a median of 9 minutes for pharmacists to complete their clinical intervention.

Information regarding medication reconciliation was obtained from the patients in 84 cases (32.8%), their caregivers in 61 cases (23.82%), patients' home medication bags in 43 cases (16.79%), their insurance records in 58 cases (22.65%) and other sources in 4 cases (1.56%) (Figure 1).

Figure 1: Source of information for medication reconciliation



DISCUSSION

The impact of medication reconciliation by pharmacists on the rate of medication errors was evaluated in this study. Our results showed that medication histories taken by pharmacists were more comprehensive than routine drug histories taken by nurses. We also observed that pharmacist interventions can have a positive impact on the rate of medication errors.

Results of various studies indicate the high that rate of different types of medication errors and related burden in hospitalized patients especially through admission or discharge process as well as transferring from one unit or facility care to another. These errors are mainly the result of miscommunication and lack of required information and can lead to serious complications [5, 14, 15, 16]. Our results showed a high rate of medication errors in our study population, especially during the discharge process. We observed that errors related to the dose of patient medications were the most common errors. While in some other studies various types of medication errors, as well as errors in drug administration, were observed with almost the same frequencies [19].

Medication reconciliation, as a method for identifying and correcting medication errors, is widely used in health care settings in different countries [17]. The results of a systemic review showed that medication reconciliation can significantly decrease the frequency of different types of medication errors (17 from 17 studies), and drug side effects (2 from 2 studies) [18]. Different studies indicate that a large number of patients admitted to hospitals, experience medication discrepancies that can be prevented by careful medication reconciliation by pharmacists [20, 21]. We also observed in the present study, that different types of medication errors can be avoided by performing a careful medication reconciliation by a trained pharmacist especially when a patient is admitted to the hospital. This can prevent any discrepancies between what has been taken at home and what is ordered in the hospital.

About two-thirds of the complications that occurred after discharge are due to medication-related problems. Generally, medication reconciliation at discharge could be a strategy to reduce medication errors and improve patient safety even after discharge from the hospital [22].

CONCLUSION

In the present study, the impact of medication reconciliation by a pharmacist, on the rate of medication errors was evaluated. The results showed a significant difference between the history taken by the pharmacists and nurses. It should be noted that although the process of medication reconciliation by pharmacists is time-consuming and need considerable human and financial resources that may be difficult to afford now, its positive impact on direct and indirect costs of medication errors cannot be dismissed. Our findings also indicated that the involvement of a trained pharmacist in patients' treatment teams can significantly improve their safety profiles.

Acknowledgments

We would like to express our particular thanks to the patients and all the hospital staff involved in this study.

Evaluation of muscle atrophy after sciatic nerve defect repair – experimental model

Andrei Marin[1,6], Mihai Savescu[2], Georgiana G. Marin[3], Anica Dricu[4], Sorin Parasca[1,5], Carmen Giuglea[5,6]

Abstract: *Peripheral nerve injuries are one of the most important causes for disability generating considerable costs around the world. Appropriate assessment of the extent of peripheral nerve lesions and the choice of the right therapeutic protocol remain some of the biggest challenges. Non-invasive neuroimaging approaches are suitable in managing peripheral nerve repairs, providing in the same time accuracy details in structural neural detection, with minimal discomfort at a low cost. Medical imaging technology development has led to progress in examination of peripheral nervous system, using a series of tools and methods, such as: ultrasonography (US), positron emission tomography (PET), magnetic resonance imaging (MRI) and magnetic diffusion tensor imaging (DTI). In this study, we evaluated the regeneration process in Wistar rats after sciatic nerve defects repair with 4 different techniques (i.e. nerve graft, rat aorta used as a nerve conduit, rat aorta filled with platelet rich plasma (PRP) and rat aorta filled with stem cells) by using MRI investigation alongside the clinical evaluation. Our results showed that among the 4 batches, the PRP batch had the best results in muscle atrophy condition (both on MRI scan and on gastrocnemius index); on the second place the stem cell batch, then the nerve graft batch and finally the aortic conduit batch. MRI proved to be a reliable non-invasive monitoring method and showed good result in correlation with the footprint test (sciatic functional index) and the gastrocnemius index.*

Keywords: *muscle atrophy, sciatic nerve, platelet rich plasma*

INTRODUCTION

Nerve injuries can be extremely debilitating due to the many functions that a peripheral nerve may have. The sensitive nerves are responsible for acquiring information such as temperature, pressure, shape, while motor nerves are important in muscle contraction and movement. These injuries are even more severe when they translate into nerve defects, which require a special type of bridging in order to recover its original function.

After the nerve is repaired it takes a long period of time for regeneration. This is due to the fact that after the nerve is sectioned, Wallerian degeneration occurs, which represents a disintegration of the axon distal to the injury site [1]. Afterwards, the growth cone leads the regeneration process through the modified Schwann cells – the Bungner columns [2]. The nerve growth rate is considered to be 1 mm/day in humans and 1.5-2 mm/day in rats. Several imaging instruments and techniques are currently used in examination of peripheral nerves: ultrasound (US), positron emission tomography (PET), magnetic resonance imaging (MRI), diffusion tensor imaging (DTI).

Nerve ultrasound is capable of assessing not only the size, but also the morphology and it may be used in diagnosing different types of peripheral nerve pathologies. The most common findings using ultrasound examination are nerve enlargement, followed by other abnormalities such as increased hypo-echogenicity or increased intraneural vascularization [3,4]. Moreover, ultrasound investigation can also asses the surrounding environment, being helpful for determining the etiology of the neuropathy (compression, trauma).

PET represents an imagistic investigation in which a radioactive tracer such as [18F] FTC-146 is injected into the bloodstream and it concentrates at the level of the nerve injury, [5] investigation which is used in order to detect the area of the neuropathy. Diffusion tension imaging (DTI) evaluates the movement of water molecules in different biological structures. DTI can evaluate a nerve injury both in terms of quantity and quality [6].

As its great similitude to the human nerve, the sciatic nerve of the Wistar rat is the perfect candidate for experimental nerve surgery. The sciatic nerve divides into 3 main branches – tibial, common peroneal and sural nerve.[7] The tibial nerve innervates the gastrocnemius muscle. Therefore, the regeneration process of the sciatic nerve can be evaluated by assessing the function, weight and diameter of this muscle.

Nerve defects can be solved by several techniques – either nerve grafts or different surgical protocols type. Defects up to 70 mm can be bridged by one of these options. [8] Nerve grafts can be either autologous or heterologous, while nerve conduits can be biologic or synthetic. [9,10] Better results were obtained by using the nerve protocol technique in combination with different substances which contain growth factors. [11] Among these, platelet rich plasma (PRP) has proven its efficacy in nerve regeneration. [12,13,14] Stem cells, similar to PRP, also have a positive impact in nerve regeneration. [15,16,17]

A footprint test in rats undergoing surgery, became a useful evaluation asset since Bain and MacKinnon introduced a formula which could calculate the sciatic functional index (SFI) based on 3 parameters-plantar length, intermediary interdigital length and the maximum interdigital distance. [18]

This study aims was to compare the regeneration process in Wistar rats after sciatic nerve defects using 4 different techniques (i.e. nerve graft, rat aorta as a nerve protocol, rat aorta filled with platelet rich plasma (PRP) and rat aorta filled with stem cells) by using MRI investigation and comparing it to the results obtained from the footprint test (sciatic functional index) and the gastrocnemius index.

MATERIAL AND METHODS

The research was conducted on 40 Wistar rats, from Carol Davila University (Convention no. 7491/21.03.2019). They were accommodated in plastic cages, receiving normative murine food and water.

The rats were divided into 4 groups – nerve graft group, aortic conduit group, aortic conduit with PRP and aortic conduit with stem cells. All rats underwent surgery with a right side approach. The biologic materials used (PRP and aortic conduits) were obtained by sacrificing 2 extra rats. The stem cells used, originated from human bone marrow mesenchymal stem cells (hBM-MSC cell line) were obtained from Life Technologies. All other chemicals were purchased from Sigma–Aldrich. The study was approved by the Ethics Committee of Veterinary Faculty (approval No. 1738/ 17.04.2019).

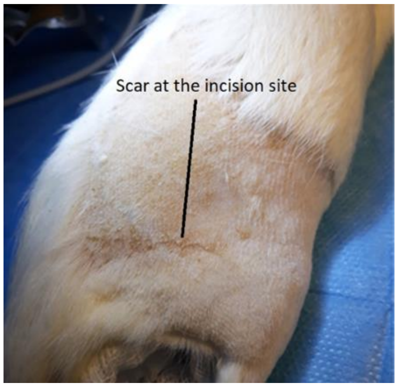
Preoperative assessment

All rats were weighed before surgery and they were anesthetized using a cocktail of 75-100 mg/kg ketamine and 10 mg/kg xylazine. The anesthetic injection was administrated intraperitoneal, maintaining anesthesia for one hour. If the rat presented signs of waking up, a second dose could be administrated.[19]

Surgical procedure

The surgical protocol was the same for all subjects. The rat was positioned in prone decubitus, than a surgical incision was performed along the right femur, 0.5 cm inferior to the bone. The biceps femoris was then dissected and right beneath it the sciatic nerve could be found.

Figure 1: Incision site (12 weeks postoperative scar)



Nerve graft

After nerve exposure, the sciatic nerve was sectioned at 2 sites to create a 0.5 cm nerve graft. In the first batch this graft was sutured in place, while in the other batches the graft was discarded, leaving a 0.5 cm defect. In the first batch, the epineural vessels served as guide to ensure correct alignment between the nerve endings.

Simple aortic conduit

Two rats were sacrificed and their aortas were taken from the heart to the bifurcation into the common iliac arteries. The aortas were then divided into 6-7 mm long segments to serve as nerve material for the next interventions. In the 2nd batch, the aortic conduit was used to bridge the nerve defect by suturing the nerve endings 1 mm inside the vessel conduit.

PRP treatment

The 3rd batch used PRP inside the aortic conduit. After extracting 2 ml of blood directly from the heart, the blood was centrifuged for 5 minutes at 4000 rpm in order to obtain PRP material. The PRP was placed inside the aortic conduit and sutured to the nerve endings.

Mesenchymal stem cell treatment

In the 4th batch, mesenchymal stem cells from human bone marrow were used. These were transported in liquid nitrogen at -196oC and defrosted using the following protocol: cryogenic tube extraction, 500 µL phosphate-buffered saline (PBS) solution was added, then the solution was centrifuged for 5 minutes at 1500 rpm and the supernatant was disposed of; the last 3 steps were repeated and after obtaining the stem cells, they were suspended in Ringer solution. The stem cells were then included in the aortic conduit and this was sutured to the nerve endings.

The immediate postoperative treatment included antibiotic therapy using enrofloxacin at a dose of 0.003 mg/kg (Enroxil) and an anti-inflammatory drug (meloxicam 1 mg/kg) administered subcutaneously for 3 days.

Postoperative assessment

All subjects were evaluated at 2, 4, 6, 8, 10 and 12 weeks after surgery, including sensitive and motor evaluation, as well as a footprint test. At 12 weeks all rats were sacrificed using KCl after an overdose with the above mentioned anesthetic. The gastrocnemius muscles were evaluated using MRI imaging and then they were harvested and weighed (bilateral).

Walking footprint analysis

The SFI (sciatic functional index) represents a fairly objective test which evaluates the peripheral nerve regeneration in rats and mice. The method consists of recording, measuring and calculating the dimensions of the footprints of the studied rats after unilateral sciatic nerve injury. Monte-Rasso has demonstrated that this index is measurable and reproducible starting the 3rd week after the nerve lesion. [20]

The traditional method of recording the footsteps involves using paper and ink, but it can record many artifacts which could affect the results. The development in technology by using an infrared system eliminated this problem and reduced the effort of the investigator. [21]

The formula for the SFI introduced by Bain and MacKinnon takes into account foot values of both the operated and the non-operated limb. A value close to 0 indicates normal function, while -100 represents complete function loss:

$$SFI= 38.3 \times EPL-NPL/NPL + 109.5 \times ETS-NTS/NTS+ 13.3 \times EIT-NIT/NIT - 8.8.$$

where EPL – plantar length (operated limb), NPL – plantar length (non-operated limb), EIT – intermediary interdigital length (operated limb), NIT – intermediary interdigital length (non-operated limb), ETS – maximum interdigital distance (operated limb) and NTS – maximum interdigital distance (non-operated limb)

Magnetic Resonance Imaging (MRI)

The imagistic investigations were conducted at the Veterinary Medicine Faculty in Bucharest using an MRI scanner Vet-MR Grande Esaote de 0.2 T. A standard spin echo pulse protocol with T1 and T2W in sagittal, dorsal and transversal planes was performed. This protocol included a girth of 2mm/slice and 0,5mm distance between slices. Due to the small size of the rat, an articulation human coil was used.

The rat was examined in prone position in the MRI coil, with both inferior limbs in extension. The thorax and the head of the rat were sustained on 2 sponges during the investigation. Each rat required 15-20 minutes for the investigation and 5 minutes for preparation. On the transverse sections, the calf diameters were measured (right and left) and then a ration between the 2 values was calculated.

For the MRI calf muscle ratio (right/left), the measurements were performed on anaesthetized rats lying in prone position, with both inferior limbs extended. The image selected for measurement was the first imagine in transverse plane where the limbs appeared attached to the body.

Gastrocnemius muscle – operation and measurements

After incising the dorsal skin of the calf in the midline and dissecting through the superficial flat muscle, the gastrocnemius muscle revealed. It was then harvested from the level of Achilles' tendon to its origin on the femur. Using an electronic scale, the weight of the gastrocnemii muscles were measured and the ratio between operated and non-operated side was noted.

Statistical analysis

To process the data obtained, we used IBM Statistical Package for Social Science (SPSS) - Median test for the continuous variable analysis, where the median and the Inter Quartile Range (IQR) were reported. The threshold for statistical significance was $p<0.05$.

The correlations between continuous non-parametric variables were performed using Kendall Tau b test. The representation of the data was done using box-plot graphics and scatter-dot and line diagrams.

RESULTS

40 male Wistar rats of similar weight and age were used for research, divided into the 4 studied groups and 2 extra rats were used to harvest biologic materials. All rats underwent a surgery on the right sciatic nerve. 2 rats from the first batch were excluded from the study – one due to postoperative death and the other one due to a ruptured sciatic nerve. The rat who suffered a nerve rupture was kept until the end of the study (12 weeks).

The variables taken into account for nerve regeneration were:

- right and left gastrocnemius muscle weight and their ratio recorded at 12 weeks
- ratio between the right (operated) gastrocnemius muscle weight and the rat weight at 12 weeks (percentage)
- SFI at 6 and 12 weeks
- right and left calf diameters and calf diameter ratio recorded via MRI at 12 weeks

The MRI investigation could identify the nerve and the aortic nerve conduit in transverse, coronal and sagittal plane. The calf diameter could be measured bilaterally and the calf ratio could be calculated.

The images below describes the position of the sciatic nerve (lying inferior to the femur). One image shows the nerve graft in T1 sequence, while the other one shows the aortic conduit in T2 sequence. No image can however reveal the suture sites in any of the sequences.

After completing the MRI scanning, the rats were euthanized and the gastrocnemius muscles were harvested bilaterally. A fine electric scale was used to weigh each muscle. These gastrocnemius ratios were compared to the MRI ratios for all batches.

Peripheral nerve regeneration after nerve graft intervention

In the nerve graft batch, the SFI at 6 weeks varied between -83 and -69, while at 12 weeks it was between -60 and -50. The right calf diameter at the end of the study ranged between 15.35 and 17.97 mm. The left calf diameter had values between 19.96 and 22.04 mm. The calf diameter ratio varied from 0,76 to 0,84. The median values for the variables reported via MRI scanning are presented in tables 1 and 2.

The gastrocnemius muscles on the operated side weighed between 1.22 and 1.49 g while the non-operated muscles weighed between 2.27 and 3 g. The gastrocnemius muscle weight ratio varied from 0.45 to 0.65. The median values for the variables associated to gastrocnemius muscles are presented in tables 3 and 4 and those for the SFI values in Table 5.

Peripheral nerve repair with rat aorta graft

In the second batch, the SFI varied at 6 weeks between -83 to -73, while at 12 weeks between -63 and -49. The right calf diameter had values between 13.78 and 17.81 mm, while the left one was between 18.2 and 21.73 mm. The calf diameter ratio varied from 0.74 and 0.84. The median values for the variables reported via MRI scanning are presented in Tables 1 and 2.

The gastrocnemius muscles on the operated side weighed between 0.65 and 1.58 g while the non-operated muscles weighed between 2.06 and 2.86 g. The gastrocnemius muscle weight ratio varied from 0.29 to 0.69. The median values for the variables associated to gastrocnemius muscles are presented in tables 3 and 4 and those for the SFI values in Table 5.

The effect of platelet rich plasma (PRP) treatment on peripheral nerve repair

In the third batch, the SFI varied at 6 weeks between -80 to -71, while at 12 weeks between -62 and -48. The right calf diameter had values between 15.11 and 17.71 mm, while the left one was between 18.56 and 21.53 mm. The calf diameter ratio varied from 0.74 to 0.84. The median values for the variables reported via MRI scanning are presented in Tables 1 and 2.

The gastrocnemius muscles on the operated side weighed between 0.77 and 1.61 g while the non-operated muscles weighed between 2.28 and 2.73 g. The gastrocnemius muscle weight ratio varied from 0.34 to 0.67. The median values for the variables associated to gastrocnemius muscles are presented in Tables 3 and 4 and those for the SFI values in Table 5.

The effect of mesenchymal stem cells transplantation on peripheral nerve repair

In the third batch, the SFI varied at 6 weeks between -78 to -72, while at 12 weeks varied between -62 and -51. The right calf diameter had values between 15.65 and 17.88 mm, while the left one was between 19.38 and 21.73 mm. The calf diameter ratio varied from 0.78 to 0.81. The median values for the variables reported via MRI scanning are presented in Tables 1 and 2.

The gastrocnemius muscles on the operated side weighed between 1.17 and 1.46 g while the non-operated muscles weighed between 2.26 and 2.76 g. The gastrocnemius muscle weight ratio varied from 0.48 to 0.54. The median values for the variables associated to gastrocnemius muscles are presented in Tables 3 and 4 and those for the SFI values in Table 5.

Comparison of the 4 methods for the repair of peripheral nerve injury

SFI

The median values for SFI recorded at 6 weeks indicated better recovery in nerve graft batch, followed by the PRP and simple aortic conduit batches and the stem cell batch. At 12 weeks, the median values for SFI showed a very good recovery in the PRP batch, followed by stem cell and nerve graft batches, while the poorest results were recorded in the simple aortic conduit batch.

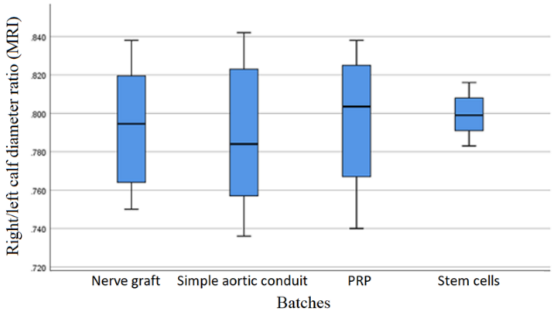
MRI test

The right (operated) calf diameter had the highest median value in the nerve graft batch, followed by the stem cell batch and simple aortic conduit and PRP batches with similar results. The same order was recorded on the left side as well. The highest calf diameter ratio (right/left) recorded via MRI scanning was in the PRP batch, followed by the stem cell batch, and the nerve graft batch, without statistical difference (p=0.753).

Gastrocnemius muscle

There were no statistical differences in the 4 batches when referring to the weight of the right gastrocnemius muscle. The highest median was in the nerve graft batch, followed by PRP batch, then stem cells batch and finally simple aortic conduit batch. The left one had the highest median value when referring to the weight variable in the nerve graft batch; followed by stem cell batch and then the PRP patch and last – the simple aortic conduit batch.

Figure 8: Distribution graphic of the MRI right/left calf diameter ratio for all batches



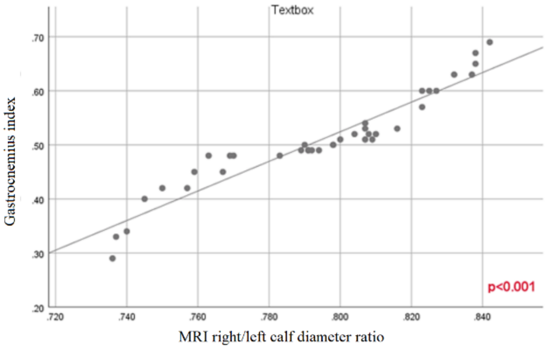
The median for the gastrocnemius index – the best results were in the PRP batch, followed by the stem cells batch, then the nerve graft batch and finally the simple aortic conduit batch. There were, however, no statistical differences between these batches.

The highest median when evaluating the percentage obtained from the right gastrocnemius muscle and the rat weight at 12 weeks was recorded in the PRP batch, all other batches obtaining similar results. Like the previous test, no statistical difference was achieved here either.

Using the Kendall Tau analysis, there were 4 positive statistical significant correlations (Table 7): MRI right/left calf diameter ratio – gastrocnemius index; MRI right/left calf diameter ratio – SFI at 6 weeks; MRI right/left calf diameter ratio – SFI at 12 weeks; gastrocnemius index (right/left) and SFI at 12 weeks.

The statistical analysis revealed a strong positive correlation between the MRI right/left calf diameter ratio and the gastrocnemius index. (r=0.95, p<0.001).

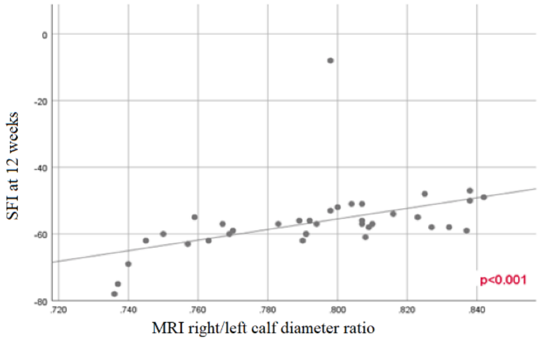
Figure 9: Correlation graphic between gastrocnemius index and MRI right/left calf diameter ratio



The statistical analysis revealed a strong positive correlation between the MRI right/left calf diameter ratio and the SFI at

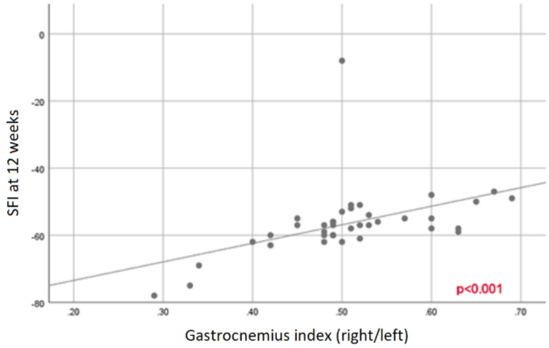
6 weeks (r=0.3, p=0.010) and at 12 weeks (r=0.485, p<0.001).

Figure 10: Correlation graphic between MRI right/left calf diameter ratio and SFI at 12 weeks



There was also a strong positive correlation between the gastrocnemius index and the SFI at 6 weeks (r=0.323, p=0.007) and at 12 weeks (r=0.487, p<0.001).

Figure 11: Correlation graphic between gastrocnemius index (right/left) and SFI at 12 weeks



DISCUSSION

The MRI could not reveal the sciatic nerve in all the sections due to its small size. A high-performance MRI scanner (1,5 T or 3T) might be useful in identifying the extent of the lesions as well as small structures (fascicles of the human sciatic nerves), and a better and more detailed aspect of the suture sites.

Tremp et al used a 3T MRI scanner to assess regeneration in a rat sciatic nerve injury model. They were capable of visualizing the nerve graft by observing a small black outline, while the regenerating axon front could be seen as a small hyperintensity. The study also used the 3T MRI scanner to monitor the regeneration progress using the 2 types of stem cellular therapy (autologous and human stem cells). [24]

Muscle imaging and MRI in particular has become an important tool in the diagnosis of muscle diseases – both inherited and acquired. Subclinical progression of the different muscular diseases can be detected using quantitative muscle MRI techniques. [25]

Although MRI scanning could offer non-invasive information about nerve regeneration by observing the degree of muscle atrophy, this investigation is unlikely to become a gold standard as it reveals the negative effects at a late stage (when there is severe muscle atrophy). The gastrocnemius index can only be used in experimental studies and, similar to the previous investigation, it reveals the negative results only when it is too late (as the muscle atrophies progressively).

The MRI right-left calf diameter ratio could be correlated with the right-left weight gastrocnemius muscles ratio (gastrocnemius index) and with the SFI from the footprint test. The correlations between these indicators are justifiable, as all of them evaluate the degree of muscle sparing as a result of nerve regeneration process. Similar studies of MRI calf muscle evaluation after partial and complete denervation have been conducted on mice. The muscle atrophy was estimated by volume measurements on MRI, which were correlated to the post-mortem muscle weight examination. [26]

Nijhuis et al used a similar correlation to observe gastrocnemius muscle atrophy after sciatic nerve injury but instead of the MRI scanner, they used ultrasound imaging to asses muscle volume. Their study showed that the difference between the muscle thickness ratio (via ultrasound) and the muscle mass ratio was no more than 5%. [27] In clinical practice, ultrasound examination can therefore prove to be a reliable and accesible tool for muscle mass measurements. [28]

Another study conducted by Shen et al showed that the SFI parameter after sciatic nerve injury has positive correlations with indices such as electrophysiology, muscle strength and morphology. This research confirmed that the SFI can be a reliable index for nerve regeneration. [29]

A reliable investigation for nerve lesions is the electrophysiologic study. Vleggeert-Lankamp et al showed in a study using electrophysiological analysis that the ionic channels of both the Aalpha- and Abeta-fibers are altered after nerve injury and the correlation between nerve morphometry and electrophysiology is most suitable for evaluating nerve regeneration. [30]

Another study conducted by Shen et al used an electrical field for nerve regeneration purposes. They performed morphometric, electrophysiologic and functional evaluations on days 10, 20, 30 and 60 after the operation. Their research proved that direct current electrical stimulation facilitates peripheral nerve growth. [31]

Martins et al assessed recovery after sciatic nerve injury using several tests: electrophysiology, sciatic functional index (SFI) and histomorphometry. Using Pearson's analysis, they noticed 2 positive correlations with statistical significance (between the SFI and proximal nerve fiber diameter and between the SFI and distal nerve fiber diameter), thus concluding that there are few correlations between the 3 evaluation methods. [32]

With the evolution of technology, the imagistic evaluation of the peripheral nerves via MRI changed from the classical morphological studies to functional neurography. This new technique involves using diffusion tensor imaging and diffusion-weighted sequences and provides information (both functional and morphological) about the internal structure and physiopathology of the peripheral nerves. [33]

The magnetic resonance neurography (MRN) is the salvage solution for complex cases. The spacial distribution of the peripheric nerve helps with the classification of the peripheric nerve injuries in traumatic plexopathies or partial neuropathies of the fascicles. [34]

MRN has some important advantages: it is not operator dependent, it offers 3D representation of the entire nerve, it has great soft tissue contrast, and it provides detailed images of the nerve structure, fascicles and its surrounding environment. For these reasons, MRN is a suitable investigation for tumors, traumas (including the evaluation of brachial plexus injuries), as well as compressive lesions. [35]

Neurography is particularly useful in the cases where nervous lesions are less obvious (compression syndromes or partial nerve injuries); this investigation is capable of establishing the degree of the nervous injury, directing the therapeutic approach.

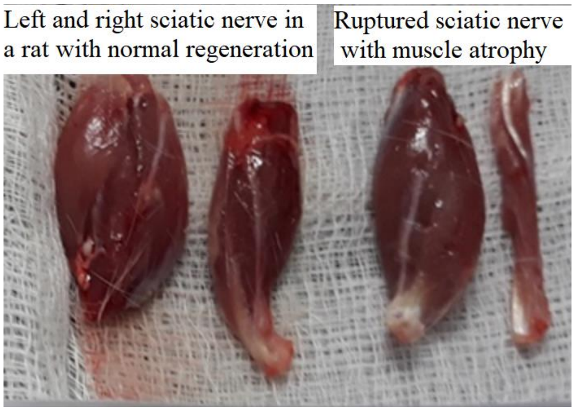
Microstructural defects of the peripheral nerves can nowadays be detected using quantitative diffusion tensor imaging. (DTI) The imagistic depiction on MRN of the smaller nerve branches can be improved by vascular suppression techniques and parallel imagining, which provides a higher spacial resolution. [36]

The gastrocnemius index was a quantifiable measurement in assessing nerve regeneration. A gastrocnemius index close to the value of 1 (meaning that the weights of the 2 gastrocnemius muscles – right and left - are similar) represents the normal value of a non-operated rat, with muscles that did not undergo atrophy. A very low value of this index indicates severe muscle atrophy, due to a poor nervous regeneration (or a lack of nerve regeneration).

The rat with the ruptured sciatic nerve in the first batch was taken out of the study in order not to influence the results. However, it was useful in order to observe the degree of muscle atrophy when no repair was performed and also as a reference in order to compare regeneration in the 4 batches.

While the median value of the gastrocnemius index for the 38 rats included in the study was 0.5, the gastrocnemius index for the rat with the ruptured nerve was 0.18. However, not having more rats in the category of the unrepaired sciatic nerve, no statistical analysis could be performed.

Figure 12: Two pairs of gastrocnemius muscles in 2 different rats



Left and right sciatic nerve in a rat with normal regeneration
Ruptured sciatic nerve with muscle atrophy

The positive correlation between the gastrocnemius index and the sciatic functional index at 6 and 12 weeks can be explained by the fact that both indicators are influenced by the degree of the calf muscle recovery.

CONCLUSIONS

Nerve regeneration can be properly evaluated only after a period of time. The MRI right-left calf diameter ratio represents a non-invasive investigation complementary to the gastrocnemius index as they both evaluate the same aspect in the process of nerve regeneration – the degree of muscle atrophy. Therefore, there was a strong correlation between these 2 investigations.

None of the repair methods tested showed a statistical significant advantage regardless of the test used to evaluate nerve regeneration.

The effect of muscle atrophy was reflected in the footprint test and therefore the sciatic functional index could be correlated to the MRI right-left calf diameter ratio.

Development in technology will provide better imagistic methods to monitor the regeneration stages after peripheral nerve injury both at the site of the injury, as well as at the site of the innervated organ.

Evaluation of epidemiological characteristics, treatments, and prognosis of patients with COVID-19 hospitalized in the Intensive Care Unit

Seyed M.A. Zavareh[1], Seyed A.A. Zavareh[2], Razieh Bakhtiari[3], Marzieh Lak[4]

Abstract: *Introduction: Intensive care facilities may play an important role in reducing corona mortality. This study aimed to assess the epidemiological features, treatments, and prognosis of corona patients that admitted to the Intensive Care Unit (ICU) of Baqiyatallah Hospital.*

Methods: All patients with a corona that admitted to the ICU of Baqiyatallah Hospital from March 5 to May 20, 2020, were included. The epidemiological characteristics, pharmacological, non-pharmacological, and supportive therapies and prognosis were assessed. Underlying diseases, smoking, and severity of lung involvement based on CT scan findings (mild, moderate, severe) and length of hospital stay in the ICU were recorded in a questionnaire. Non-invasive ventilation (NIV) or tracheal intubation, ventilator ventilation, and duration of endotracheal intubation, if needed, were recorded in the questionnaire. Meanwhile, whether tracheostomy was performed, the time of the procedure, and its duration were also recorded.

Results: Overall, 82 patients were included in the study that 68 (82.9%) of them were males. The mean age was 57.96±14.08 years. The mortality rate was 53 cases (64.6%). There were 57 subjects (73.1%) at a severe lung involvement and 21 subjects (26.9%) at a moderate lung involvement. There was a significant relationship between severity of lung involvement and mortality (Odds ratio= 14.3, P<0.001).

There was a significant relationship between mortality and Armadile use (Odds ratio= 2.9, P=0.04). There was a significant relationship between mortality and tracheal intubation (Odds ratio= 27.2, P<0.001). There was no significant difference between mortality and discharge of patients regarding the intubation period (P=0.26). There was not a significant relationship between tracheostomy, NIV, and mortality status in the patients (P=0.14 and 0.33 respectively). Also, there was no significant difference between mortality and discharge of patients regarding tracheostomy and NIV period (P=0.51 and 0.17). There was no significant difference in age between severe and moderate lung involvement cases (P=0.63). There was a significant difference in the duration of ICU hospitalization between severe and moderate lung involvement cases (P=0.004).

Conclusion: The results showed none of the factors of age, sex, underlying diseases other than hypertension, pharmacological methods other than Armadile, and non-pharmacological methods such as hemoperfusion, plasmapheresis, IVIG, hyperimmune plasma injection, and stem cell as well as Ozone therapy does not affect corona patient's mortality. Only the severity of lung involvement leading to endotracheal intubation and mechanical ventilation is related to patients' mortality

INTRODUCTION

In December 2019, the world faced a great challenge. A respiratory disease caused by the coronavirus that causes severe acute respiratory syndrome (SARS) in patients and endangers the health of people around the world [1].

Treatment of these patients is supportive and usually respiratory failure is the main cause of death [2]. The clinical features and CT scan images help in the early diagnosis and treatment of this disease [3].

This disease’s mortality has been stated 3.6% in China and 1.2 to 1.7% outside of China. the difference between these statics is because of not considering patients with mild illness and taking diagnostic tests. The actual number of deaths is unknown [4].

Intensive care facilities may play an important role in reducing the risk of COVID-19 death [5].

In this retrospective study, we surveyed the epidemiological features, treatments, and prognosis of patients with coronavirus admitted to the ICU of Baqiyatallah Hospital, that we may identify preventable factors associated with the patient recovery and reduce mortality of these patients.

METHODS

In a retrospective study from March 5 to May 20, 2020, all patients with COVID-19admitted to ICU of Baqiyatallah Hospital were evaluated for their epidemiological characteristics, pharmacological, non-pharmacological, and supportive therapies, and prognosis. "Baqiyatallah Hospital is one of the important referral medical centers for corona patients in Iran."

The diagnostic criteria for Corona Patients are clinical symptoms, positive PCR test, and CT scan findings in this center. Hospitalized patients with respiratory distress or SPO2 with oxygen and storage bag below 90% in general wards and emergency departments were transferred to ICU.

Epidemiological characteristics of patients including age, sex, underlying diseases, smoking and Drug abuse, the severity of lung involvement based on CT scan findings (mild, moderate, severe), and length of hospital stay in the ICU were recorded in a questionnaire.

All drugs used in the treatment of patients, as well as non-pharmacological methods including antibody therapy, plasmapheresis, hemofiltration with Jeffron filter, hyperimmune plasma, IVIG, CRRT with cytosorb filter, stem cell, and other methods, were recorded in the questionnaire.

NIV or tracheal intubation, ventilator ventilation, and duration of endotracheal intubation, if needed, were recorded in the questionnaire. Meanwhile, whether tracheostomy was performed, the time of the procedure, and its duration were also recorded.

The data were analyzed by SPSS-22 software. Quantitative data were analyzed using descriptive software and displayed as Mean ± SD. Chi-Square tests were used to compare percentages or frequencies. A P-value less than 0.05 was considered statistically significant.

RESULTS

Overall, 82 patients were included in the study that 68 (82.9%) of them were males. The mean age was 57.96±14.08 years. The mortality rate was 53 cases (64.6%). Table 1 showed the distribution of age, sex, duration of hospitalization in the ICU, and history of diabetes mellitus (DM), hypertension (HTN), kidney disease, liver disease, rheumatic disease, smoking, opium addiction, corticosteroid use, and ARBS regarding mortality of the patients.

The mean age was 59.59±13.85 years in mortality cases and 55.03±14.24 years in discharge patients. There was no significant difference in age between mortality and discharge of patients (P=0.16). Also, there was not a significant relationship between gender and mortality (P=0.76(.

There was not a significant relationship between mortality and DM, kidney disease, lung disease, liver disease, and rheumatic disease in the patients (Table 1). However, there was a significant relationship between mortality and HTN (Odds ratio= 2.99, P=0.04) (Table 1).

There was not a significant relationship between mortality and smoking, opium addiction, corticosteroids, and ARBS in the patients (Table 1).

Table 2 showed the distribution of pharmacological treatment regarding the mortality status of the patients. There was a significant relationship between mortality and Armadile use (Odds ratio= 2.9, P=0.04) (Table 2).

Table 3 showed the distribution of tracheal intubation, intubation period, tracheostomy, tracheostomy period, NIV, NIV period regarding the mortality status of the patients.

There was a significant relationship between mortality and tracheal intubation (Odds ratio= 27.2, P<0.001) (Table 3). The mean intubation period was 3.50±2.83 days in mortality cases and 2.81±2.22 days in discharge patients. There was no significant difference between mortality and discharge of patients regarding the intubation period (P=0.26).

	No	40 (75.5%)	19 (65.5%)	59 (72.0%)	
NIV period, days, mean (±SD)		3.63±2.20	2.54±1.43	3.09±1.90	0.17

** P-value is significant at the 0.05 level.*

There was not a significant relationship between tracheostomy, NIV, and mortality status in the patients (P=0.14 and 0.33 respectively). Also, there was no significant difference between mortality and discharge of patients regarding tracheostomy and NIV period (P=0.51 and 0.17) (Table 3).

Table 4 showed the distribution of mortality, age, tracheostomy, duration of ICU hospitalization, tracheal intubation, intubation period, tracheostomy, tracheostomy period, NIV, NIV period regarding the severity of the disease of the patients.

There were 57 subjects (73.1%) at a severe lung involvement and 21 subjects (26.9%) at a moderate lung involvement (Table 4). There was a significant relationship between severity of lung involvement and mortality (Odds ratio= 14.3, P<0.001).

The mean age was 58.05±13.43 years in severe lung involvement cases and 55.19±15.15 years in moderate lung involvement cases. There was no significant difference in age between severe and moderate lung involvement cases (P=0.63).

The mean duration of ICU hospitalization was 15.59±10.61 days in severe lung involvement cases and 8.85±5.78 days in moderate lung involvement cases. There was a significant difference in the duration of ICU hospitalization between severe and moderate lung involvement cases (P=0.004).

49 cases (86.0%) in severe lung involvement had tracheal intubation There was a significant relationship between the severity of diseases and tracheal intubation (P<0.001). The mean intubation period was 3.30±2.32 days in severe cases and 4.12±4.96 days in moderate cases. There was not a significant difference in the intubation period between severe and moderate lung involvement cases (P=0.86).

Also, 34 cases (59.6%) in severe lung involvement had a tracheostomy. There was a significant relationship between the severity of diseases and tracheostomy (P<0.001). There was not a significant difference in the tracheostomy period between severe and moderate lung involvement cases (P=0.74).

There was not a significant relationship between NIV and the severity of disease in the patients (P=0.15). The mean NIV period was 3.44±1.91 days in severe lung involvement cases and 1.50±0.57 days in moderate lung involvement cases. There was a significant difference in the NIV period between severe and moderate lung involvement cases (P=0.026) (Table 4).

DISCUSSION

Overall, 82 patients were included in this study that 68 (82.9%) of them were males. The mean age was 57.96±14.08 years. The mortality rate was 53 cases (64.6%).

There was a significant relationship between mortality and history of HTN, Ardamadil use for treatment, the severity of lung involvement, and tracheal intubation. There was no significant relationship between NIV and the severity of lung involvement in the patients. There was a significant difference in the NIV period between severe and moderate lung involvement cases.

The mean duration of ICU hospitalization was 15.59±10.61 days in severe cases and 8.85±5.78 days in moderate cases. There was a significant difference in the duration of ICU hospitalization between severe and moderate cases

Daniel E L Promislow and colleagues concluded that aging is associated with increased complications of corona and that men of all ages have more serious complications than women [6].

Qirong Ruan and colleagues in a study of hospitalized corona patients concluded that age had a significant effect on mortality and gender had no significant effect. Underlying diseases, secondary infections, and high levels of inflammatory factors in the blood are predictors of high mortality [7].

However, in this study, patient's age and sex did not have a significant relationship with mortality. Maybe the reason that gender didn’t have a significant relationship with mortality in this study was that this study included patients admitted to the ICU and patients with critical situations were being transferred to this sector., and this statistic is different from the general mortality statistics in the society.

As in previous studies, Mandeep R. et al. Concluded heart diseases were associated with increased mortality in hospitalized corona patients. In their study, the use of ACEIs and ARBs was not associated with an increase in mortality [8].

In a meta-analysis of 1576 patients with COVID 19, JingYang and colleagues concluded that underlying diseases such as hypertension, heart disease, and respiratory disease were more common in critically ill patients than in less critically ill patients [9].

Marcello Covino et al. concluded that the use of ACEIs or ARBs in corona hypertensive patients was not associated with increased mortality [10].

In this study, in line with Mandeep R. and JingYang studies, blood pressure had a significant relationship with mortality. Also, in line with the study of Mandeep R. and Marcello Covino, the use of ACEIs and ARBs had no significant relationship with mortality.

Thomas C. Hanff and colleagues stated that corona hypertensive patients treated with ACEIs should not change their treatment regimen [11].

While Lei Fang and colleagues found that diabetes, heart disease, and hypertension were factors associated with corona disease severity, they suggested replacing calcium channel blockers with ACEIs or ARBs [12].

Li-Lin Liang and colleagues found that higher mortality rates could be due to fewer testers. Also, an older population, weak government, and a small number of beds can increase mortality [13].

A study by YUNPENG JI et al. In China concluded that the reason for the high mortality rate in HUBEI (2.9%) compared to other Chinese provinces (0.7%) was probably due to the rapid increase in the number of infections around the outbreak center. Which has led to insufficient health resources [14].

CONCLUSION

According to the results of this study, none of the factors of age, sex, underlying diseases other than hypertension, pharmacological methods other than Armadile, and non-pharmacological methods such as hemoperfusion, plasmapheresis, IVIG, hyperimmune plasma injection, and stem cell as well as Ozone therapy does not affect corona patient’s mortality. Only the severity of lung involvement leading to endotracheal intubation and mechanical ventilation is related to patients’ mortality, so according to studies by Li-Lin Liang and YUNPENG JI, it can be concluded that The most important factor in reducing patient mortality is the management of the disease epidemic, which makes adequate treatment resources available to patients and no patient dies due to lack of facilities in severe epidemics. And in epidemics, special attention should be paid to hypertensive patients.

Evaluation of fasting impact during Ramadan month on patients with a history of kidney stones in a military hospital

Mousa Asadi[1], Hasan Nazari[1]

Abstract: *Introduction: One of the cornerstones and common causes of kidney stone formation is the volume of fluid consumed during a 24- hour that influences on forming that by several mechanisms. Since fluid intake decreases during Ramadan, one of the common questions posed is whether Ramadan fasting is associated with the precipitating of stone formation. The present study was aimed to investigate the effect of Ramadan fasting on precipitating and Inhibitors of stone formation in patients with a history of renal kidney disease.*

Methods: The study population included all of the patients with kidney stone diseases who were seen at the Clinic of Urology and Nephrology affiliated with Baqiyatallah hospital during the month of Ramadan in 2014 and 2015. The number of 66 patients was chosen and included in the study through randomized simple sampling. All subjects underwent blood tests like serum uric acid, serum phosphate, serum calcium, and serum sodium. Samples were tested in terms of volume, magnesium, uric acid, Calcium, Phosphate, Sodium, citrate, oxalate, Calcium oxalate supersaturation, Calcium Phosphate supersaturation, Uric acid supersaturation.

Results: Sixty-six eligible patients were included that the mean age was 48.35±12.10 years. Fourteen men and 52 women were included. There were no significant differences in the mean pH of urine, urinary sodium, urinary oxalate, super-saturated levels of calcium oxalate in the urine, urinary phosphate levels, and super-saturated levels of urinary calcium phosphate between the two groups (P>0.05). The average volume of urine, urinary magnesium, urinary calcium, urinary citrate, the uric acid level in the non-fasting group was higher than the fasting group (P<0.05). There were no differences in the average blood calcium levels, blood sodium, blood phosphate levels, blood acidic levels between the two groups (P>0.05). There was no difference in the mean super-saturated level of uric acid between the two groups (P=0.035).

Conclusion: There was controversial evidence on the effect of Ramadan fasting on kidney stone formation and there is not enough evidence in the present study that Ramadan fasting precipitates risk factors associated with calculus formation

Keywords: *fasting, kidney calculi, inhibitor factors, and precipitating factors*

INTRODUCTION

Ramadan month is related to the Islamic calendar and is a holy month for Muslims. Healthy adult Muslims should be fasting during this month and the times spent on fasting maybe change from 12 to 18 hours depending on the seasonal and regional specialties. Any food and fluid eating are allowed only from sunset to sunrise in this month. Islam rules permit the break of fasting for particular people including unhealthy cases [1-5].

However, many Muslim patients reveal their willingness to keep the fast during Ramadan month to regard religious cultures. There are concerns regarding the influence of

[1] Nephrology and Urology Research Center, Baqiyatallah University of Medical Sciences, Tehran, Iran

dehydration and the consequent renal hypoperfusion in Ramadan fasting for patients with renal illnesses [6]. This problem especially arises when Ramadan month happens during hot and dry summers with a long daytime span.

In the Ramadan month, fasting Muslims tend to alter their dietary habits. This involves changes in eating times and the content of food, in addition to fluid deprivation. It is fairly well known that fluid deprivation causes volume con-traction and renal hypoperfusion. The latter may cause renal dysfunction and aggravate existing renal impairment [7-9].

There is scarce scientific data about the safety of Ramadan fasting for patients with different renal diseases. The existing published reports are mainly focused on the impact of Ramadan fasting on patients with renal transplantation, patients with chronic kidney disease, and patients with the renal stone disease [10-12].

One of the cornerstones and common causes of kidney stone formation is the volume of fluid consumed during a 24- hour that influences on forming that by several mechanisms [13-15]. Since fluid intake decreases during Ramadan, one of the common questions posed is whether Ramadan fasting is associated with the precipitating of stone formation. The present study was aimed to investigate the effect of Ramadan fasting on precipitating and Inhibitors of stone formation in patients with a history of renal kidney disease.

METHODS

The study population included all of the patients with kidney stone diseases who were seen at the Clinic of Urology and Nephrology affiliated with Baqiyatallah hospital during the month of Ramadan in May 2016 and May 2017. The number of 66 patients was chosen and included in the study through randomized simple sampling. The sample size of the study consisted of 66 kidney stone patients (30 patients in the fasting and 36 patients in the nonfasting group). The case group was examined for three weeks after one week from the beginning of the holy month of Ramadan and their laboratory factors were recorded.

Inclusion criteria were included the presence of kidney stones at the time of referral or a history of kidney stones proven by ultrasound or CT scan, did not use drugs that affect the aggravation or treat of the kidney stones, did not use a diet that affects stone formation (Including frequent consumption of nuts such as nuts or frequent consumption of chocolate containing cocoa. Cola drinks, a high-salt or meaty diet, and plenty of citrus fruits). Also, patients with chronic liver disease, advanced cardiac disease, acute infection, or diabetes insipidus were excluded. All cases were fulfilled the consent form and they have consented to fast in Ramadan.

Collecting data was done by a Researcher-built Form. All subjects underwent blood tests like serum uric acid, serum phosphate, serum calcium, and serum sodium. Samples were asked to urinate for the first time at 9 a.m. and to be expelled. The urine is then poured into a special container until 9 pm and the entire urine collected within 12 hours is delivered the next day. Clinical evaluation of the patients included meticulous current and past medical history, and physical examination. Urine samples were tested in terms of volume, magnesium, uric acid, Calcium, Phosphate, Sodium, citrate, oxalate, Calcium oxalate supersaturation, Calcium Phosphate supersaturation, Uric acid supersaturation. Uric acid was calculated using the Tiselius formula in both groups. The evaluation of the patients was conducted near the end of the month of Ramadan.

After being collected, the data was inserted into SPSS software (Statistical Package for Social Science Version 20) and analyzed by using descriptive statistics and statistical tests such as t-Tests and the Mann-Whitney. A P-value of less than 0.05 was considered significant.

RESULTS

Sixty-six eligible patients were included. The mean age was 48.35±12.10 years. Fourteen men and 52 women were included. There were no differences between the two groups regarding age and gender (P=0.12 and 0.14 respectively).

Table 1: Demographic characteristics of all participants in the two groups

Groups	Non-fasting	Fasting	P-value
Age	48.3±13.37	43.4±11.06	0.118
Gender, M/F	8/28	6/24	0.452

There were no significant differences in the mean pH of urine, urinary sodium, urinary oxalate, super-saturated levels of calcium oxalate in the urine, urinary phosphate levels, and super-saturated levels of urinary calcium phosphate between the two groups (P>0.05) (Table 2).

The average volume of urine, urinary magnesium, urinary calcium, urinary citrate, the uric acid level in the non-fasting group was higher than the fasting group (P<0.05) (Table 2).

There were no differences in the average blood calcium levels, blood sodium, blood phosphate levels, blood acidic levels between the two groups (P>0.05) (Table 2).

There was no difference in the mean super-saturated level of uric acid between the two groups (P=0.035) (Table 2).

Table 2: Biochemical characteristics of all participants in the two groups

Groups	Non-fasting	Fasting	p-value
Blood Ca level	9.4±0.52	9.3±0.83	0.567
Blood Na level	141.80±2.01	140.80±1.91	0.101

Urine acid uric level	208.59±73.49	154.90±66.57	0.004
Extra acid uric level	0.50±0.23	0.80±0.72	0.35

DISCUSSION

In this study, the effect of fasting during Ramadan month on the improvement of the urinary system was examined. The concept of ultra-stable saturation is due to the excessive increase in the constituent salts of the stone, such as calcium, phosphorus, oxalate, and uric acid in the urine, and the solubility of these minerals in the urine. It seems that the lack of saturation in non-stone individuals is due to the activity of crystallization inhibitors. These inhibitors include magnesium, citrate, phosphate ions, and coarse molecules such as Tamm-Horsfall protein. In the case of low inhibitors and the ability to form stone, the constituent salts of the stone adhere to the rock crystals and from these crystals, nodules or stone nuclei and finally from the enlargement of these nodules, one-millimeter pebbles and the enlargement and the accumulation of these pebbles form larger stones. Also, other conditions such as urinary saturation, increased deposition of kidney stones such as calcium, oxalate, uric acid, and phosphate, urine pH, decreased urine volume, the presence of crystallization facilitators such as uric acid, infection, acidity, and pointed to insoluble ions. The results of the present study showed that the level of uric acid in the blood, the level of calcium in the blood, the level of sodium in the blood, the level of urinary phosphate, the level of urinary sodium in non-fasting people is higher than in fasting people. On the other hand, urine volume, urinary magnesium, uric acid, calcium urine, total urine volume, and urinary citrate in non-fasting individuals were higher than in fasting individuals, which was statistically significant. Ultrasonic levels of calcium phosphate in the urine of fasting patients are higher than those of non-fasting patients but were not statistically significant.

In general, among the blood parameters involved in the formation of kidney stones, only the level of blood phosphate in the fasting group is higher than the fasting group, but statistically, this difference was not significant. According to the findings of this study, the average level of urinary citrate, urinary magnesium, urine volume in the fasting group is lower than the fasting group. The high levels of these three act as crystallization inhibitors and the low levels in fasting people provide the basis for the formation of kidney stones. But statistically, only urine volume and urine citrate among the above inhibitors were significantly lower in the fasting group than in the fasting group. They reduce the growth of crystals and their accumulations and prevent the formation of secondary nuclei. Facilitators refer to molecules that reduce the supersaturated surface needed to initiate the crystallization process. The imbalance between these two sets of factors is more important than other factors in the formation of kidney stones. These substances include organic compounds, proteins, and glycosaminoglycans.

In this study, the urine volume of fasting people was lower than that of non-fasting people. Excessive fluid intake has been a traditional treatment in recent decades, and doctors have been prescribed to prevent kidney stones in patients with kidney stones. The results of studies on the effect of urine volume on kidney stone formation are: Low volume of urine is considered as a risk factor for the onset of kidney stone formation and re-formation of kidney stone, an increase in urine volume due to excessive fluid consumption. It has a positive effect on the prevention of kidney stones and does not interfere with the normal activity of inhibitors. Mass consumption of liquids such as water, coffee, tea, beer has a deterrent effect on reversibility and kidney stone formation. Everything is in dispute and is always controversial. Therefore, high fluid intake, especially water, is considered an effective and economical method in preventing the formation of kidney stones, which is often ignored by people who have kidney stones [16]. In a study by Cheh et al., Which was conducted to investigate the effect of fasting on urinary excretion, the results showed that the volume of urine was reduced by 24 hours in resinous individuals, but this decrease was not significant. In this study, 24-hour urine volume was divided into three time periods, urine volume in the morning, evening, and night. In this study, the volume of nocturnal urine in the previous periods and the length of Ramadan have remained unchanged, and Ramadan does not affect the volume of nocturnal urine. But the volume of urine in the evening was less than in the pre-Ramadan period, and this decrease was significant. Which is consistent with the results of this study. Also, a decrease in urine in the second and third weeks was significant in fasting people, but in the last week of Ramadan, it was not significant, which is largely consistent with the findings of this study. Decreased urinary volume, indicating low fluid intake or loss of excess water, directly increases the risk of kidney stones by increasing the saturation of stone-forming salts in the urine. Fasting may limit fluid intake and, by affecting urine concentration and chemical composition of the blood, prepare the ground for the formation of kidney stones [17]. Magnesium is the fourth most abundant mineral in the body and is intentionally located in the bones. The magnesium in the diet is absorbed in the small intestine and excreted by the kidneys.

The normal amount of 12-hour urine magnesium is between 0.15 and 0.5. Only 0.1% of all magnesium in the body is mobile. Magnesium can combine with oxalate to reduce supersaturation. Oral magnesium intake reduces the absorption of oxalate and urinary excretion. Magnesium can also combine with calcium in the gut. Magnesium supplements increase the excretion of citrate in the urine during magnesium deficiency [18]. According to the findings of this study, the mean level of urinary magnesium in fasting people is significantly different from fasting people, so that its level is lower than in fasting people. In the study of Miladipour and colleagues, the level of urinary magnesium in fasting people Dar was higher than non-fasting people, but it was statistically insignificant, which differs from the findings of this study [19]. Zegal et al. investigated the effect of fluid and dietary restriction restrictions on fasting on the biochemical factors of kidney stone formation. In this study, 90 patients were divided into three groups of healthy fasting people (those without kidney stones), healthy people without fasting, and people with kidney stones without fasting. The results of this study showed that the mean inhibitory level of urinary magnesium among fasting groups without kidney stone disease is lower than non-fasting individuals, which is quite consistent with the results obtained in this study [19]. Another inhibitor of kidney stone formation is citrate, which is present in the form of trichloroxyl acid in the blood and combined with calcium, magnesium, and sodium at a pH of 7.4. Most citrate is derived from exogenous aerobic metabolism, which is freely cleared in the glomerulus. Approximately 75% of the filtered citrate is absorbed in the complex proximal open tubule. Hypothyroidism (low levels of citrate in the urine of 320 mg per day) is seen in more than 50% of people with kidney stones. The normal 12-hour urinary titrate is 0.6 to 4.8. Hypothyroidism is caused by a variety of factors, including medications such as acetazolamide and thiazides, renal acidosis, urinary tract infection, hypokalemia, low magnesium, and inflammatory bowel disease [20]. In the study of Zegal et al. Mentioned above, the level of citrate in fasting people was lower than in non-fasting people, which is consistent with the findings obtained in this field [19].

In this study, the mean urinary citrate level in the non-fasting group was higher than the fasting person, which was statistically significant. In the study, Miladipour et al. [19] in which 57 people participated, 37 had recurrent kidney stones and 20 had no kidney stones. Urine readings in three 24-hour urination periods before Ramadan (period 3), urination during Ramadan, and hours 19 to 15 (period 1), and urine was collected during Ramadan from 15 to 19 (4 hours urine as period 2). In this study, the amount of urinary citrate in people in the pre-Ramadan period (group 3) was lower compared to fasting people (group 1 and group 2), which contradicts the findings of this study. One of the facilitators of kidney stone formation in this study was uric acid. To form uric acid-containing stones, uric acid must be highly saturated in the urine. There are usually three main factors involved in the formation of uric acid-containing stones, including acidic urine, hyperuricemia, and low urine volume. Hyperuricemia is the excretion of more than 600 mg of uric acid per day in 24-hour urine. The degree of hyperuricemia is directly related to kidney stones [21]. High uric acid levels may be due to overproduction of uric acid in the body or reduced urinary excretion. In particular, the factors that increase the concentration of uric acid in the blood are diuretics, hypothyroidism, obesity, excessive alcohol and coffee consumption, genetic factors, etc. One of the findings of this study is The average uric acid level in the urine of fasting people was significantly higher than in fasting people. In the study of Miladipour et al. [19]. The mean uric acid level for 24-hour urine in non-fasting individuals was higher than the 24-hour uric acid level during Ramadan, but statistically, there was no significant difference following the findings of this study. Findings on uric acid and blood uric acid measurements show three major facts. 1. High concentrations of acid in the blood are due to decreased uric acid excretion in the urine, and low concentrations of urine are associated with increased uric acid. During fasting, a small portion of the uric acid that enters the nephrons from the blood is reabsorbed (reabsorbed.) There is a significant exchange of uric acid between the tissues and the blood for 24 hours a day.

12-hour normal urinary calcium is less than 250 mg. The results of this study showed that urinary calcium levels in fasting people were significantly lower than those without fasting. A study by Miladipour et al. [19] showed that the level of calcium in the urine of fasting people was significantly higher than that of fasting people, which is quite consistent with the results of this study. The concentration of calcium in the urine also indicates the concentration of calcium in the blood. The difference between urinary calcium levels in the two study groups appears to be due to the type of food and activity level, age, geographical location, and source of drinking water. Hyperoxaluria is an excessive increase in urinary oxalate (normal 12-hour urinary oxalate is between 0.23 and 0.68). In this study, urinary oxalate levels in the fasting and non-fasting groups did not differ significantly from each other. In the study of Miladipour et al. [19] the level of urinary oxalate in non-fasting and fasting people was not significantly different from each other, which is consistent with this study. Increased levels of oxalate in the urine of people are caused by factors such as diet or inflammatory bowel disease [22]. One of the major studies on the combination of calcium and oxalate is the cohort study conducted by Korhan et al. On 45619 men. After 4 years, 8.7% of the samples developed kidney stones. In this study, an inverse relationship was found between calcium intake and the formation of calcium-oxalate (CaOx) compounds [23]. Robertson's study found that there was a linear relationship between urinary oxalate levels and the formation of kidney stones, as well as the prevalence of kidney stones in different countries and the excretion of oxalate in the urine [24]. In general, 80% of calcium-based stones are oxalate calcium stones. In one study, randomized clinical trials of people with hypercalciuria were divided into two groups with low calcium and oxalate diets and one group with high calcium diets but oxalate, salt, and low protein. After five years, the renal stone recurrence rate in the second high-calcium group was reduced to 51% [25]. The results showed that the super-saturated levels of calcium oxalate in the urine were slightly lower in the fasting person than in the fasting person, but this difference was not significant. The amount of calcium oxalate in the urine may be altered by factors such as diet and fluid intake. Similar to the results of this study, in the study of Miladipour et al. [19] there was no significant difference between the mean calcium oxalate levels in fasting and non-fasting individuals, and also the desired variable was not significantly different in people with kidney stones during Ramadan and before Ramadan. In addition, there was no significant difference between healthy individuals during Ramadan and before Ramadan in terms of the average level of oxalate. Brochite ($CaHPO_{42}H_2O$) is the main cause of kidney stones of calcium phosphate origin. Urine in people who have kidney stones (which contain calcium) is saturated with super-high brushes due to the high concentration of calcium. Calcium is a type of calcium phosphate, but at least supersaturation is required for the formation and survival of rock containing calcium phosphate, because, in the lower levels of supersaturation, the primary nucleus of rock formation usually dissolves. All phosphates are calcium, containing calcium and phosphate ions. It is believed that the primary nucleus of calcium-containing rocks is calcium phosphate. Although calcium phosphate rocks may form in a supersaturated gaming solution, their formation in PH Urine is not known to be normal (26). In this study, the mean saturated level of urinary calcium phosphate in the fasting group was higher than the fasting population and this difference was statistically significant. In the study of Miladipour et al. [19], urinary phosphate is lower during fasting than before fasting, but it is statistically meaningless. The variability of calcium phosphate levels in the urine is influenced by factors such as diet and especially fluid intake, which is different for fasting and non-fasting days, but during Ramadan, there is not much difference for urine during different periods. In the study of rust, the amount of bruschetta was the same for healthy people fasting and people with kidney stones and without fasting, but for healthy people without fasting, this amount was less, which is consistent with our study. The excretion of uric acid in adults is 500 to 600 mg in 24 hours (the normal amount of uric acid in normal urine for 12 hours is less than 480).

The concentration of solution and pH plays an important role in the solubility of urate uric acid. However, the formation of uric acid stones is not common. Most people with an abnormal PH6 in their urine have urine saturated with uric acid, but they do not form a stone. More acidity (such as a pH of 3.5) or dehydration is needed to make a stone. Uric acid, which is not highly soluble, crystallizes at low pH and forms rock. The normal amount of uric acid in the blood is very important for the proper functioning of the body. The normal level of uric acid in the blood is between 0.3 and 0.7 mg / dL. Uric acid is formed in the human body system as a byproduct of purine metabolism and then excreted in the urine.

This means that the difference seems to be small due to various factors such as diet, urine volume, and dehydration, but this difference was not statistically significant. In the study of Miladipour et al. [19] the mean uric acid saturation level in the 4-hour evening urine (maximum concentrated urine) was higher than the pre-Ramadan uric acid saturation level and was statistically significant, which is consistent with our study. However, this rate is lower in the urine sample from 19:00 to 15:00 the next day than in the pre-Ramadan period. A small amount of sodium is absorbed from the stomach, but most are absorbed quickly through the small intestine. The absorbed sodium is carried by the bloodstream to the kidneys, where the sodium is purified and returned to the blood in the amount needed by the body. When the need for sodium increases, the action of some hormones stimulates the reabsorption of sodium by the kidneys. Conversely, when sodium intake increases, the secretion of these hormones decreases to reduce sodium retention. The amount of sodium in the urine depends on the daily diet, increases when consumption is high, and decreases when consumption is low. The increase or decrease in sodium in the blood should not exceed 0.5 to 1 mg/l. In the present study, the mean blood sodium level in the group of non-fasting people was higher than the fasting people, but this difference was not statistically significant. Also, the urinary sodium level of non-fasting people was higher than the fasting person, but this difference was not statistically significant.

In Miladipour's study, the amount of 24-hour sodium in non-fasting people was higher, but it is statistically meaningless, which is consistent with the present study. A study by Sakhai et al. showed that increasing the intake of sodium chloride from 140 to 310 mmol/L increases the amount of urinary calcium by 34% and reduces the amount of urinary citrate by 10%. Therefore, hyponitrite and calcification are among the main factors in the formation of kidney stones, which are caused by increased sodium chloride consumption [27]. In a study by Brutis et al., The results showed that sodium chloride salt consumption played a stronger role in increasing urinary calcium and the risk of stone formation compared to calcium and protein intake [28]. Consumption of sodium chloride salt is considered an indicator of the ratio of sodium to potassium in the urine [29]. The amount of normal 12-hour urinary phosphorus is between 1300-300. The average level of urinary phosphate in the non-fasting group was higher than in the fasting person, but this difference was not statistically significant. In Miladipour's study [19], the rate of 24-hour urinary phosphate in non-fasting individuals was higher and statistically significant, which is consistent with the present study. Decreased urinary phosphate levels in fasting people occur due to factors such as prolonged starvation during Ramadan.

The amount of phosphate reference in the adult blood is 2.7 to 4.5 milligrams per deciliter (mg/dL) or 0.87 to 1.45 milliliters per liter (mmol/L), which helps the kidneys control the amount of phosphorus in the body and excess phosphorus. It is filtered through the kidneys and excreted in the urine [30]. One of the serum factors studied in this study is the level of uric acid in the blood. The average level of uric acid in the blood of fasting people was higher than fasting people, but this difference was not statistically significant. In the study of Goma and colleagues, the serum uric acid level was compared with the serum uric acid level in the pre-Ramadan period at 6 am, 6 pm, and after iftar. Serum uric acid levels did not change at 6 a.m. during the first two weeks of Ramadan, but serum uric acid levels increased significantly during the second two weeks of Ramadan. Serum uric acid levels were significantly reduced at 6 p.m., then increased, and almost reached the pre-fasting period limit, which is consistent with the results of this study.

One study found that the average serum levels of calcium in fasting people were lower than in non-fasting people, but the difference was not significant. Also, the total amount of urinary calcium in the fasting group was lower than in the non-fasting group. This difference is statistically significant and is fully consistent with Miladipour's study [19]. Calcium balance is mainly achieved by the absorption of calcium in the intestine, its reabsorption in the kidneys, and the exchange and transfer between bone and other tissues. Serum calcium consists of ionic and protein compounds. Calcium reacts with compounds such as phosphate and citrate. In gaming environments, the amount of free ions in calcium serum decreases. 99.99% of the calcium ingested into the kidneys is reabsorbed, thereby regulating serum and urinary calcium levels [31]. No study found a link between fasting and serum calcium levels.

CONCLUSIONS

In recent years, it has been determined that the factors involved in the formation of kidney stones include urinary saturation levels with stone-forming components such as calcium, oxalate, sodium, etc., which were studied in this study. Fasting is important to prevent stone formation in the future. In general, by examining the results of this study and other studies, it seems that fasting during Ramadan has contradictory effects on urinary stone formation factors and there is not enough evidence about the effect of Ramadan on exacerbating exposure to stone-forming factors in this study.

Evaluation of in-vitro bactericidal activity and anticancer effects of venom fractions of *Pseudocerastes persicus* snake

Majid M. Nodooshan[1], Hossein Sobati[2], Ehsan Malekara[1], Hamid R. Goodarzi[3], Firouz Ebrahimi[4], Ashkan Normohamadi[4], Jamil Zargan[4]

Abstract: *Introduction: It was reported that snake venom contains a wide mixture of proteins and peptides with various toxicological and pharmacological effects. In recent years, the isolation of effective molecules from snake venom as a drug to treatment of some incurable diseases is considered by many biological research centers. This investigation aimed to determine electrophoretic and chromatographic patterns of Pseudocerastes persicus snake venom and in-vitro study of bactericidal and anti-cancer properties of its fractions in a human hepatocellular liver carcinoma cell line (HepG2).*

Materials and methods: The fractions of venom were isolated and collected using preparative RP-HPLC. The Bactericidal activity of fractions in 20 µg/ml of protein concentration was investigated toward Gram-negative and Gram-positive bacteria. Antibacterial susceptibility tests were done using MTT and MIC assays. Furthermore, cell viability was measured by MTT reduction assay and confirmed with Neutral red uptake assay following exposure of HepG2 cancer cells to 20 and 40 µg/ml of protein concentrations of fractions having more antibacterial properties. Apoptotic effects were investigated using the comet assay.

Results: SDS-PAGE pattern of the crude venom revealed 10 major bands with molecular weight ranging from 13.2 to 99.25 kDa and the single-step separation of different fractions from the venom by HPLC resulted in isolation and collection of 11 fractions. The results of this study showed that two fractions of snake venom have significant antibacterial activity against Gram-positive as compared to Gram-negative bacteria. On the other hand, our findings indicated that one of them is not toxic to the HepG2 cells.

Discussion: We for the first time reported bactericidal and anticancer effects of isolated fractions of Persian horned viper venom. These properties make components of these fractions a favorable source for isolation of molecule(s) with antibacterial and antitumor activities.

Keywords: *snake venom, Pseudocerastes persicus, antibacterial, cytotoxicity, cancer*

INTRODUCTION

One of the serious problems of the medical community in the treatment of infectious diseases caused by bacterial agents, many bacteria are resistant to common antibiotics. These bacteria are becoming a serious clinical problem around the world (Jami al Ahmadi et al., 2010). This has

prompted pharmaceutical firms to explore new antibacterial drugs or optimize antibiotics to help them produce new and effective drugs. Nowadays poison of poisonous animals is considered by many researchers as one of the most important natural sources for the isolation and identification of antimicrobial molecules and it has been a great success.

Reports indicate that, despite that the oral and tooth smears of poisonous snakes in a wide range of pathogenic bacteria, there is a small incidence of bacterial infection in the bites of the injured patients due to snakebite (Talan et al., 1991). These observations have led the researchers to point out that antibacterial compounds are found in Snake (Deivy et al., 2005).

The first report on antibacterial activity in the venom poison the families of Alpidea and Vipride was published in 1948 and 1968 respectively (Ferreira, 1956). Also Skarnes in 1970, for the first time reported antimicrobial activity in some of the enzymes found in the venom of snakes (Aloof-Hirsch et al., 1968). Studies of Zey et al. in 2000 also led to the isolation of peptides from Naja atra, which in vitro inhibited the growth of resistant bacteria of Mycobacterium tuberculosis and showed inhibitory activity (Xie et al., 2003).

Studies show that molecular compositions and especially proteins present in the veniphil genus of the Viperidae variety are very diverse. Important compounds of these toxins include serine protease, metalloproteinase, phospholipase A2 (PLA2), C-type lectin, acetylcholinesterase, L-aminoacids, and detergents (Markland, 1997).

Recent studies have shown that many of these compounds have antimicrobial properties (Jami al Ahmadi et al., 2010; Stabeli et al., 2004; Lu et al., 2002).

In this study, the antibacterial effects of protein fractions isolated from Pseudocerastes persicus snake and the anti-cancer effects of fractions with antibacterial properties were studied.

MATERIALS AND METHODS

Venom preparation

To prepare the venom from the snake, the snake venom safety tips were placed directly into the venom collection jar, and the venom was briefly injected into the venous gland. The toxic solution was kept at minus 20 °C until lyophilization until use in the experiments.

Microorganisms and cell lines used

Bacillus subtilis subsp. spizizenii a gram-positive and non-pathogenic bacteria (ATCC 6633), bacteria Escherichia coli a gram-negative bacteria (ATCC 25922), and pathogen Staphylococcus aureus a gram-positive bacteria (ATCC 25923) were prepared from the Persian Type Culture Collection (PTCC) of Iran and liver cancer cells (HepG2, C158) of Pasteur Institute of Tehran cell bank.

Studying the crude venom electrophoresis pattern using SDS-PAGE method

To study the electrophoresis pattern of crude venom of Pseudocerastes persicus snake, 12-15% gel (Chellapandi and Jebakumar, 2008) was applied to each well of 5-10 microliters of toxic solution (containing 20 to 15 micrograms of protein) denatured with an appropriate volume of sample buffer was injected.

Standard protein was used to estimate the molecular weight of protein bands.

Electrophoresis first started at 50 V and after passing the dyeing gel through the concentrating gel, electrophoresis continued at 150V until the color of the tracing reached about 1 cm from the end of the gel cassette. After staining the gel with coma blue and removing excess dye from the gel surface, the estimated molecular weight of crude venom protein bands was determined.

Isolation of crude venom fractions using Reversed-Phase High-Performance Liquid Chromatography (RP-HPLC)

Fragile venom of Pseudocerastes persicus snake using RP-HPLC preparation with UV detector (220 nm absorbance), C18 SUPELCOSIC TM Pcc-18 (59185) 250mm×21.2mm, 12μm] column and Gradient Linear Application [buffer A (acetonitrile) 20% containing 0.1% TFA) and buffer B (80% acetonitrile containing 0.1% TFA)] separated in 70 minutes. In the reverse phase method, a polar mobile and non-polar stationary phase are used and the material is separated by hydrophobicity (Steuten et al., 2007).

For the separation of crude venom fractions, 40 mg of dried powder in 20 ml of buffer (water). Containing 0.01% TFA containing 5% acetonitrile and dissolved for 2 hours at 4°C. After centrifugation, the insoluble material was removed from the suspension for 5 min at 10,000 rpm at 4°C. The supernatant was used for chromatographic patterning and fractions separation by HPLC. The corresponding fractions of each peak were collected manually in perfectly clean glassware free of any protein contamination and stored at -80°C after lyophilization. The retention time of each peak was recorded for each peak.

Protein assay

For antibacterial and cytotoxicity tests, some of the lyophilized venoms were dissolved in sterile distilled water twice. The amount of protein in the toxic solution was determined using Bradford (Bradford 1976) method and the protein-free fractions were excluded from further studies.

Examination of antibacterial properties

Culture media and antibiotics: MH (Mulberry Hinton) Company, Quelab, Canada, was used for bacterial culture. Tetracycline (Sigma, USA) at a concentration of 50 µg/ml was used to compare the effect of the venom with standard antibiotics.

Evaluation of the antibacterial effect of fractions using MTT assay

MTT assay is a colorimetric assay based on the reduction and breakdown of tetrazolium yellow crystals by the succinate dehydrogenase enzyme present in the cytoplasm and ultimately the formation of insoluble blue crystals. These crystals are soluble by the addition of DMSO (Hengwei et al., 2010). The bacterium was cultured in the Muller Hinton broth medium and then after 5 h when it reached the absorbance was equivalent to the absorbance of 0.5-McFarland (at 600 nm with an absorbance of 0.08 to 0.1) (Husniye et al., 2013). 5 µL per 96 plate sterile wells were cultivated. Fractions were added to wells at a concentration of 20 µg/ml and the final volume of each well was made up to 100 µL using a liquid culture medium (Muller Hinton Broth). In this experiment, tetracycline (50µg/ml) was used as a positive control, bacterial suspension and culture medium as a negative control, and non-bacterial culture medium as blank. The plate was incubated in the incubator for 23h at 37°C. Then 5µl MTT (5µg/ml concentration) was added to all wells. The plate was incubated at 37°C under dark conditions for one hour. Then 100 µL of DMSO was added to each well. After 2 hours of incubation in dark conditions, the absorbance of the wells at 595 nm was measured using a plate reader (Biotek, USA). The above experiment was performed 3 times and 3 wells (3 times repeated) were considered for each concentration. Bacterial viability after exposure to different concentrations of venom was calculated using the following formula (Husniye et al., 2013).

$$100 \times (a/b) = \text{Bacterial vital percent}$$

a = Optical Absorption Sample - Blank Optical Absorption
b = Negative optical absorption - Blank optical absorption

Evaluation of antibacterial effect of fractions using MIC assay

In this study, we aimed to determine the inhibitory effects of crude venom on bacteria. The steps of the minimum inhibitory concentration test (Shebl et al., 2012) were similar to the MTT assay but after incubating the bacteria with different concentrations of the venom at 37 ° C for 24 hours without adding any biomarkers, the optical absorption of the wells at the wavelength of 605 nm was measured using a plate reader (Biotek, USA). The experiment was repeated 3 times and for each concentration 3 wells (3 times). The percent inhibitory effect of the standard venom and antibiotic effect was calculated using the following formula (Shebl et al., 2012).

$$100 \times (a/b)]-1[= \text{Inhibitory percentage of bacteria}$$

a = Optical Absorption Sample - Blank Optical Absorption
b = Negative optical absorption - Blank optical absorption

Anti-cancer properties of fractions

Cell culture:

To eliminate possible contamination in the toxic solution required by cellular tests, 1% antibiotic-antimycotic (Invitrogen, USA) was added and used in experiments at 4°C overnight.

DMEM-F12 medium (Gibco, USA) containing 10% FBS (Fetal Bovin Serum) prepared from the company (Gibco, USA) was used for HepG2 cell culture. These cells were cultured in flasks containing 25-50 ml cube and stored at 37°C and 5% carbon dioxide. Replace the old culture medium every 2–3 days, and after providing the cell population required for each experiment using trypsin-EDTA prepared from Sigma-Aldrich, USA, isolated from the flask and after counted with neobars lam were used.

Evaluation of cytotoxicity of fractions by MTT assay

This procedure was performed according to the method of Zargan et al. (Zargan et al., 2011). For this test, 3×104 cells were cultured in 96 well plates containing 100 µl serum-free culture. After overnight incubation at 5% CO2, humidity about 80%, and 37°C, the old culture medium was discharged and the new serum-free medium containing different concentrations of 20 and 40 µg/ml of the fraction (With antibacterial properties) were added to the wells. The plate was incubated for 23 hours after incubation with the venom cell. Then 5 µL of MTT solution (5 mg/ml) was added to each well. After the formation of dark blue crystals (Formazone), the contents of each well were removed and after washing with PBS, 100 µL of DMSO was added. In this test, the culture medium was used as control and the cell culture medium as control. Optical absorption of wells at 570 nm was measured using a plate reader (Biotek, USA). The experiment was performed 3 times and 3 wells (3 times) for each concentration. The percentage of cell viability after exposure to different concentrations of venom was calculated using the following formula (Shebl et al., 2012).

% Viable cell = (a/b) × 100

a = The absorbance of treated cells - The absorbance of the blank

b = The absorbance of the control - The absorbance of the blank

Evaluation of cytotoxicity of fractions by Neutral red uptake assay

The steps of Neutral red uptake assay (Abdul et al., 2013) were similar to MTT assay but after incubating the cell adhered to the toxic solution for 23 h, one microliter of Neutral red solution (5 mg/ml) was replaced with MTT solution. Ml) was added to each well. The plate was then incubated under dark conditions at 37°C, with 5% CO_2 and about 80% moisture until red crystals (neutral red with cell lysosome surface). Then, the solution in each well was drained and after washing each well with PBS twice, 100 µl of fixative buffer (37% formaldehyde, 10% purchase). After one minute, this buffer was evacuated and 100 µL of the solvent buffer (0.5% acetic acid) was added. Plates were then incubated on a shaker for 20 minutes in dark conditions at laboratory temperature and optical absorption of wells at 540 nm was measured using a plate reader (Biotek, USA). The experiment was performed 3 times and 3 wells (3 times) for each concentration. Inhibitory percentages induced by different concentrations of venom on cell growth were calculated using the following formula.

100× (a/b)]-1 [= Percentage of cell death

a = The absorbance of treated cells - The absorbance of the blank

b = The absorbance of the control - The absorbance of the blank

Evaluation of apoptosis induction by fractions using comet assay

Comet assay or single-cell gel electrophoresis is one of the best tests for DNA fragmentation in the cell (Mir et al., 2013). For this experiment, 12×104 cells were cultured in a sterile 24-well plate containing 300 µl of serum-free medium. Plates were incubated overnight under 5% CO2, 80% humidity, and 37°C. In this test, the culture medium was used as blank and the cell culture medium was used as control. The primary culture medium was then added to each well of the test well, drained, and 300µL of a new medium (without serum) containing different concentrations of 20 and 40µg/ml of fractions (with antibacterial properties). The plate containing the cell was incubated for 24 hours at 37°C, 80% humidity, and 5% CO2. After the end of the mentioned time, cells in each well were separated by trypsin and collected in a 1.5ml tube. The microtubes containing the cells were centrifuged for 4 min at 4°C at 1500 rpm and the supernatant was discharged. The cells were washed with 400 µl of PBS (pH = 7.4) and washed after centrifugation with the supernatant and then added to 200 µl of PBS. The slides required for testing were coated with normal melting point agarose (NMA% 1), and the cell suspension with low melting point agarose (LMA% 1) was compared to one to one. Two mixtures were poured onto the slides, one slide was placed on each slide to create a cell layer, and all slides were lysed in the lysis buffer to lyse the cell and nucleus membranes. (Fresh 2.5M NaCl, 100mM EDTA, 10mM Tris, 0.2M NaOH and Triton X-100 1% pH=10) were cooled and cooled in the refrigerator for 16–18 h. After removing the sliding buffer, slides 20 the cells were washed for 2 min with electrophoresis buffer (300 mM NaOH, 1 mM EDTA, and pH> 13) and then incubated in cold electrophoresis buffer for 40 min and then incubated in the refrigerator. The electrophoresis was carried out in an electrophoretic tank containing buffer and electrophoresis was performed at 4 ° C for 45 minutes under 25 V and 300 mA current. Samples were placed in a neutral buffer (Tris 400mM, pH =7.5) for 10 min to neutralize the playing environment. For staining, cells were added to each slide with 100 µL of ethidium bromide solution at a concentration of 20µg/ml for 10 min at room temperature. The slides were then washed twice with distilled water for 10 minutes and studied by fluorescent microscopy. At least 100 cells of DNA were obtained for each sample and the results were statistically analyzed.

Statistical analysis

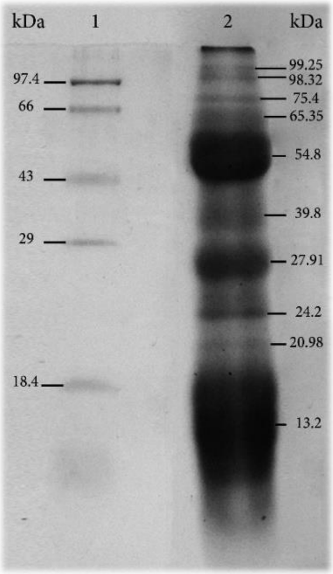
The results of each test were reported as Mean ± SD and the data were analyzed using software (GraphPad InStat). Different concentrations of venom were compared to the control group and compared to each other by one-way ANOVA and Tukey tests. P<0.05 was considered significant in all tests. Draw charts in the Microsoft Excel software (2013 version).

RESULTS

Results of crude venom electrophoresis and chromatography results

The molecular weights of the bands were determined using standard protein diagrams. SDS-PAGE (15% gel) results for 10 protein bands with molecular weight of 13.2, 19.6, 24.2, 27.91, 39.8, 54.8, 65.35, 75.4, 98.32 and 99.25 KDa Showed (Figure 1). The results of RP-HPLC separation of crude venom fractions showed 11 distinct peak peaks (Figure 2). The fractions collected were named F1 to F11, respectively, at the time of departure from the column. The fractions corresponding to each peak were collected in perfectly clean and non-contaminated glass and stored at -80 ° C after lyophilization. The retention time of the product corresponding to each courier is given in Table 1.

Figure 1: SDS-PAGE pattern (15%) of venom of the Pseudocerastes persicus snake
Column 1: Standard Protein; Column 2: the venom of the Pseudocerastes persicus snake



Protein assay: The results showed that fractions 1, 2, and 11 lacked proteins that were excluded from subsequent studies (Table 2).

Results of antibacterial tests

Results of antibacterial effect of fractions using MTT assay:

The results showed that fractions 3, 4, 7, and 9 had no inhibitory effect on Escherichia coli. But fractions 5, 6, 8, and 10 showed antibacterial effects, respectively, with the bacterial viability percentage being 81.55, 81.2, 69.87, and 71.45 % respectively. Statistical analysis showed that recent fractions had a significant inhibitory effect on bacterial growth compared to the negative control (normal culture medium containing bacteria) but their mortality rate was not significant compared to tetracycline as a positive control (Figure 3).

Figure 2: Chromatogram of unicorn raw venom of the Pseudocerastes persicus snake based on the results of R-HPLC Fractions of raw venom of Pseudocerastes persicus snake using R-HPLC preparation with a UV detector (220 nm absorbance), C18 column, and linear gradient program (buffer A: acetonitrile 20% containing 0.1% TFA and buffer B: acetonitrile 80% containing 0.1% TFA percentage was separated. The fractions corresponding to each peak were manually collected in the non-contaminated glass and the retention time of each peak was also recorded. The fractions collected were named F1 to F11 at the time of exit from the column, respectively.

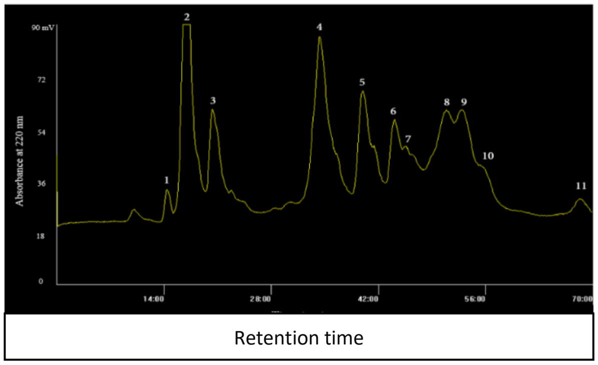


Table 1: Exit time of each component from column (in minutes)

Start time and end of peak	Fractions										
	F1	F2	F3	F4	F5	F6	F7	F8	F9	F10	F11
Start	13:50	15:36	19:22	31:14	38:27	52:51	45:01	47:50	51:59	54:56	67:06
End	15:01	19:22	24:35	38:27	42:51	45:01	47:50	51:59	54:56	59:18	69:78

Table 2: Protein content of fractions isolated from the venom

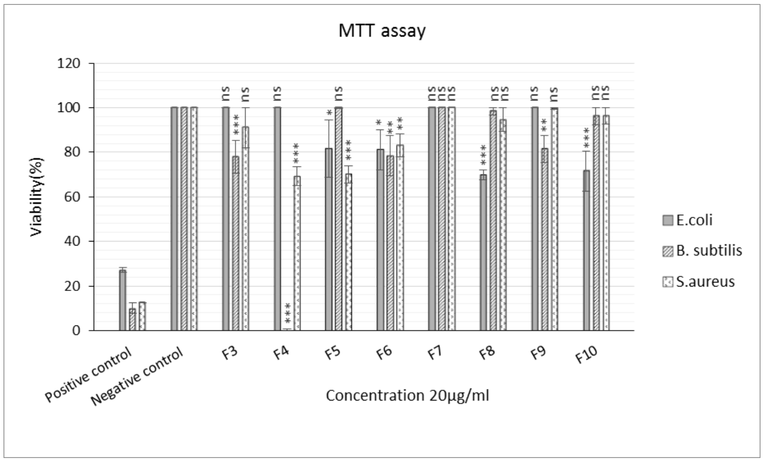
Protein concentration (mg/ml)											
Fractions	F1	F2	F3	F4	F5	F6	F7	F8	F9	F10	F11
Protein concentration	0	0.0075	1.55	11.77	10.77	6.29	1.93	12.85	11.35	4.5	0

Also, test results on Bacillus subtilis showed that its vital percentage in media containing fractions 3, 4, 5, 6, 7, 8, 9, and 10 were 78.41, 0.35, 99.91, 81.27, 100, 98.94, 81.15, and 97.49 % respectively. Fractions 3, 4, 6, and 9 had a significant inhibitory effect on the growth of this bacterium compared to negative control of growth inhibition, among which Fraction 4 had more inhibitory effect than standard antibiotic (tetracycline) (Figure 3).

The viable percentages of Staphylococcus aureus in media containing fractions 3, 4, 5, 6, 7, 8, 9 and 10 were 91.58, 69.23, 70.47, 81.38, 100, 96, 99.76, and 95.76 % respectively.

Statistical analysis of data showed that fractions 4, 5, and 6 had a significant inhibitory effect on bacterial growth compared to the negative control. The highest inhibitory effect of fractions isolated from crude venom belonged to fraction 4 with a 30.77% inhibitory effect, which was significantly less than that of tetracycline (Figure 3).

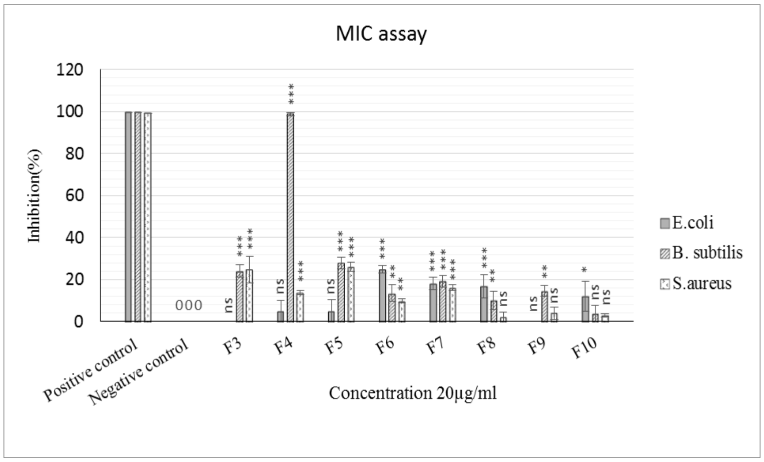
Figure 3: Critical percentages of Escherichia coli, Bacillus subtilis, and Staphylococcus aureus after exposure to 20 µg/ml protein concentration from different raw venom Pseudocerastes persicus snake fractions based on MTT assay. The effects of fractions were evaluated in comparison with the negative control group



Results of antibacterial effect of fractions using Minimum Inhibitory Concentration Method (MIC assay)

The inhibitory effects of the fractions isolated at 20 µg/ml on bacterial growth showed that fractions 3 and 9 did not affect Escherichia coli, but fractions 4, 5, 6, 7, 8, and 10, respectively 5.21, 3.48, 25.2, 17.71, 17.8 and 13.06 % had an inhibitory effect on bacterial growth. Statistical analysis showed that fraction 6 had more inhibitory effect than other fractions but this effect was not significant compared to standard antibiotics (Figure 4).

Figure 4: Percentage of Inhibitory Effect of Protein Fractions (20 µg/ml Concentration) of raw venom Pseudocerastes persicus snake on Escherichia coli, Bacillus subtilis, and Staphylococcus aureus by MIC Test. The effects of fractions were evaluated in comparison with the negative control group



The results showed that fractions Nos. 3, 4, 5, 6, 7, 8, 9, and 10 in Bacillus subtilis were 24.06, 98.46, 28.77, 13.14, 17.88, 12.30, 13.76, and 2.61, respectively produced inhibitory effects. Statistical analysis showed that mortality caused by the effect of fractions 3, 4, 5, 6, 7, 8, and 9 on bacteria was significant compared to the negative control. It is noteworthy that the inhibitory effect of fraction 4 on the growth of this bacterium was much greater than that of the positive control (tetracycline), but this effect was not significant (Figure 4).

Also, fractions 3, 4, 5, 6, 7, 8, 9, and 10 were found to be effective on the growth of Staphylococcus aureus and were

25.46, 13.85, 25.88, 9.85, 15.88, 2.28, 4.74, and 3.03%, respectively. percent inhibitory effect on it. It is noteworthy that the inhibitory effect of fractions Nos. 3, 4, 5, 6, and 7 on this bacterium was significant compared to negative control but not significant compared to standard antibiotics (Figure 4).

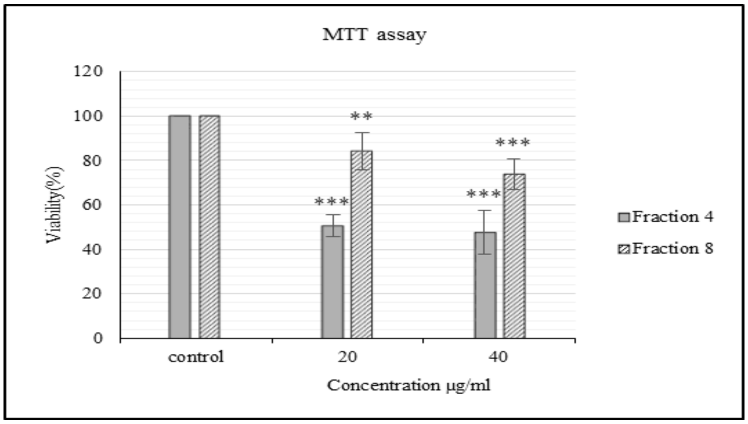
Results of anti-cancer properties of fractions

Summary of the results of the antibacterial effects of the fractions isolated from the crude venom of Pseudocerastes persicus snake and statistical analysis of data showed that fractions 4 and 8 had more inhibitory effects on the tested bacteria compared to the other fractions. Therefore, in this study, the anticancer effects and their cytotoxicity were considered.

MTT assay for cytotoxicity test results

Evaluation of cytotoxic effects of fractions 4 and 8 isolated from crude venom on the growth of liver cancer cells at two concentrations of 20 and 40 µg/ml showed that viable percentage of cells affected by fraction 4 at two concentrations compared to control, respectively, 51.55% and 50.62%. However, cell viability after exposure to fraction 8 increased at above concentrations and reached 82.29 and 74.81, respectively. Statistical analysis of data showed that the effects of fractions Nos. 4 and 8 on cell growth inhibition at two concentrations of 20 and 40 µg/ml were significant compared to control, but the inhibitory effects of the two fractions were not significant (Figure 5).

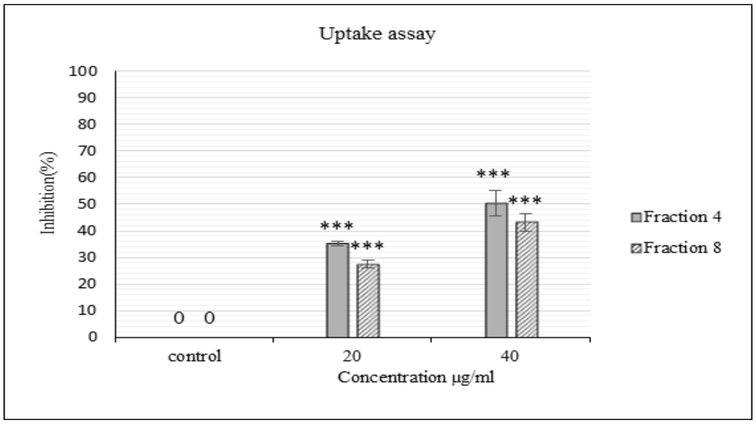
Figure 5: Vital percentages of liver cancer cells after 24 h exposure to 20 and 40 µg/ml protein concentrations of raw venom Pseudocerastes persicus snake fractions based on MTT assay. The effects of fractions were evaluated in comparison with the negative control group



Evaluation of cytotoxicity of fractions by Neutral red uptake assay

The results of the cytotoxicity study of fractions 4 and 8 using Neutral red assay showed that mortality from fraction 4 at two concentrations of 20 and 40 µg/ml in cells was 35.19 and 50.93, respectively. The percentages in the case of fraction 8 were 82.29 and 74.81 percent, respectively, which were significant compared to the control (Figure 6).

Figure 6: Mortality rate of liver cancer cells after 24 h exposure to different concentrations of raw venom Pseudocerastes persicus snake based on Neutral red uptake dye method. Mortality from the effect of each concentration was compared to the control group



Results of fractions induction of apoptosis using comet assay

The results of the comet assay showed that fraction 4 in two concentrations of 20 and 40 µg/ml had 39.31% and 38.97% and fraction 8 in the above two concentrations was 24.73% and 25.34% apoptotic, respectively. Created liver cancer cell that was significant compared to control (Figure 7–9).

Figure 7: Apoptosis rate induced by Pseudocerastes persicus snake Fragment Fraction No. 4 in Liver Cancer Cells Based on Comet Assay Test Results. The effect of each concentration was evaluated in comparison with the control

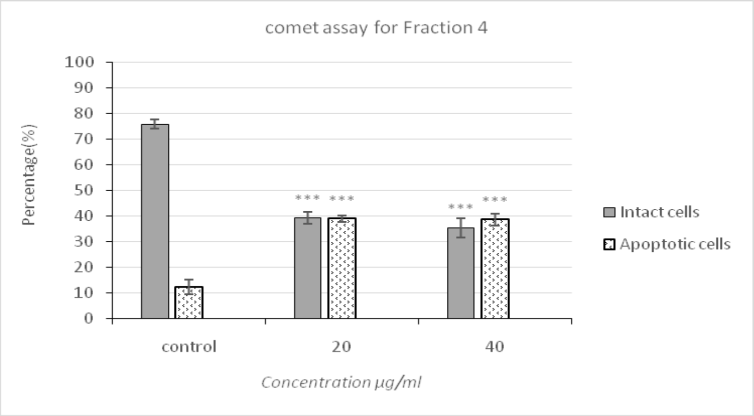


Figure 8: Apoptosis rate induced by a fraction of Pseudocerastes persicus snake number 8 in liver cancer cells based on Comet assay results. The effect of each concentration was evaluated in comparison with the control

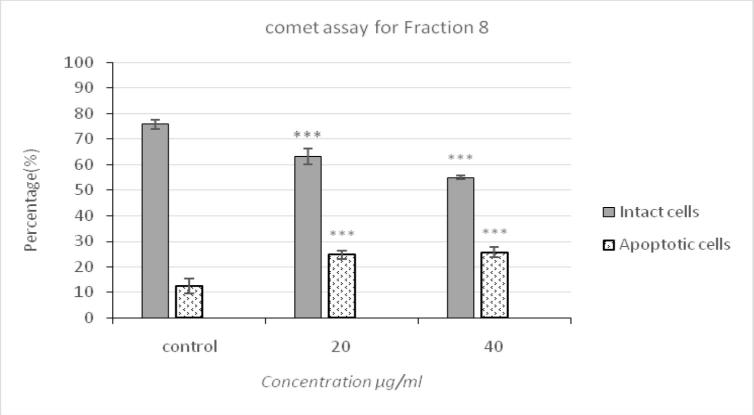

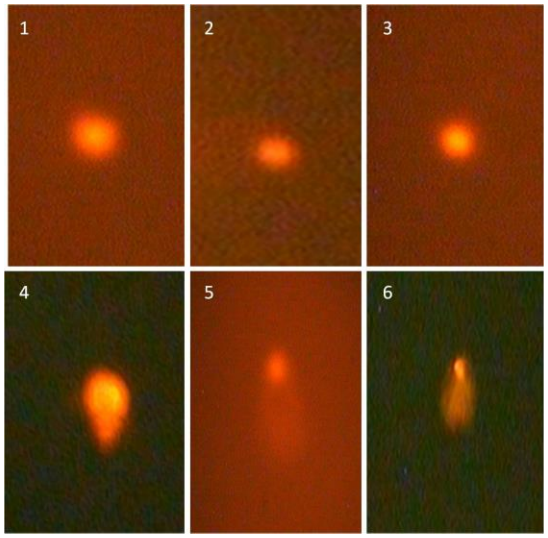

Figure 9: Morphological changes of DNA (40%) in liver cancer cells exposed to raw venom Pseudocerastes persicus snake fractions compared to control cells based on comet assay. [1-3: DNA image of healthy cells (40%), 4-6: DNA image of an apoptotic cell (40%)]

DISCUSSION AND CONCLUSION

Snake venom is a complex of molecules with different biological activities, which can be of great interest in medical and biological research (Suntravat et al., 2010). It was first carried out by researchers over 40 years ago (Master and Rao, 1961). Since the proteins and peptides present in snake venom have a wide range of molecular size as well as biochemical properties, proteomic analysis can be very important in the identification and isolation of these compounds (Phizicky et al., 2003). In the present study, a combination of electrophoretic and chromatographic methods was used to investigate the protein profile of venom. The chromatographic pattern of the venomous snake venom was studied in 2004 by Mehriyar Amini Inst using Sephadex G-50 gel filtration and 6 fractions were isolated from the raw venom (Amininasab et al., 2004).

In this study, the RP-HPLC method was used to evaluate the toxicity of the chromatographic pattern. Finally, 11 fractions were isolated and collected. Protein assay results showed that only 8 fractions of the separated fractions contained protein. In addition, our findings showed 10 protein bands in the electrophoretic pattern (SDS-PAGE). The discrepancy in the results of the electrophoresis pattern with the chromatography pattern is probably because some proteins are close to each other and are collected under a fractionation during separation.

Previous studies have shown that the pattern of electrophoresis and chromatography of different snakes is different (Nawarak et al., 2003; Rioux et al., 1998; Fry et al., 2003; Mehdizadeh-Kashani et al., 2012; Bhaskar et al., 2011). In many of these studies, by separating different components of the venom, proteins and peptides were isolated. Have been shown to have excellent therapeutic properties that can have broad implications for medicine (Barker et al., 2000; Zhao et al., 2001; Marcinkiewicz et al., 2003; Shuting et al., 2004).

The alarming growth of infectious diseases caused by bacterial resistance has prompted more research in natural resources, including the venom of various toxic animals such as snakes to discover more effective and newer antibiotics.

Based on the results of this study, it was found that the raw venom of Pseudocerastes has antibacterial properties. Also, the results showed that the raw venom of this snake against high gram-positive bacteria (Bacillus subtilis and Staphylococcus aureus) has high inhibitory effects. And against Escherichia coli only the highest concentration used (400 µg/ml) has inhibitory effects. Therefore, in this part of the study, we tried to investigate the components of raw venom, isolation, and activity of each fraction against the mentioned bacteria. MTT redaction and MIC assay methods were used for this purpose.

The results showed that fraction 4 had the most inhibitor effects on the growth of gram-positive bacteria. The inhibitory effect of this fraction was 99% on Bacillus subtilis and 31% on Staphylococcus aureus. Fraction No. 8 with 30% inhibition had the most inhibitor effect on the growth of Escherichia coli.

These results are quite consistent with the data obtained from the study of the antibacterial effects of the raw snake venom listed on these bacteria. If these fractions were selected as antibiotics for use in animals or humans, their cytotoxicity on the cell should be assessed. Therefore, the cytotoxic effects of selected fractions (with antibacterial properties) were evaluated using MTT assay, Neutral red uptake assay, and Single cell gel electrophoresis (Comet assay) on liver cancer cell line (HepG2 cell line). This part of the study showed that fraction 8 induced the least toxicity in the cell. This property introduces this fraction as a suitable candidate for the isolation of effective molecules with antibacterial properties that have the least side effects on human cells. Fraction No. 4 also induced the greatest effect on cancer cells, which, according to Comet assay results, is most likely via induction of apoptosis. Therefore, this fraction is a suitable candidate for use in drug discovery. Will be anti-cancer. Previous studies on snake venom have also shown that their venom has anti-cancer properties (Yamileth et al., 2003).

In summary, it can be concluded that the results of the present study have the potential of fraction 8 for further study as an antibiotic and fraction 4 as an anti-cancer drug.

Evaluation of morbid obese patients with attitudes toward obese persons scale prior to bariatric surgery: Obesity from the perspective of real patients

Mehmet E. Yuksel[1], Namik Ozkan[2]

Abstract: *Background: The number of studies with the application of scales, such as Attitudes Toward Obese Persons Scale (ATOP), on morbid obese patients are limited. Therefore, we wanted to examine the attitudes toward obese people through the eyes of morbid obese patients.*

Methods: Between October 2019 - April 2020, 70 female and 20 male, morbid obese patients, who were admitted to the general surgery department to be evaluated for bariatric surgery were included in this study. These 90 morbid obese patients were asked to fill out ATOP, which included 20 statements.

Results: The mean ATOP score of all morbid obese patients was 63.44±18.58 (range:19-116). The mean ATOP score of female patients was 63.47±20.34 (range:19-116), whereas the mean ATOP score of male patients was 63.35±10.69 (range:43-80) (p=0.98). The frequency of the responses given by the male and female patients to the third statement, which was "Most obese people are more self-conscious than other people" pointed out a statistically significant difference (p=0.02).

Conclusions: Based on ATOP scores gained from morbid obese patients, 60% of morbid obese patients did not feel as happy as non-obese people, whereas 74.4% of the morbid obese patients thought that obese people were not as healthy as non-obese people. Moreover, ATOP scores which were slightly higher than 60 points in both female and male morbid obese patients indicated that morbid obese patients had neither negative nor highly positive attitudes toward obese people.

Keywords: *attitude, bariatric, morbid, obesity, surgery*

INTRODUCTION

Obesity is a chronic disorder that leads to an increasing public health problem worldwide [1, 2]. Obesity has a substantial psychosocial effect on a person's life [3]. It has been suggested that 20-60% of obese patients have a psychiatric disorder.

Depression, eating disorders such as binge eating, anxiety, low self-esteem, decreased quality of life, emotional neglect, stigma and discrimination have been associated with obesity. As weight loss improves the psychosocial functioning, psychosocial effects of obesity should be considered in the management of patients especially prior to bariatric surgery [4].

Obese patients may encounter stigmatization and weight bias not only at school and work but also within their social environment. Stigmatization refers to presence of negative perceptions toward obese patients, whereas weight bias refers to negative attitudes and beliefs toward obese patients without a reason. Attitudes of stigmatization and weight bias have been investigated in various study populations such as healthcare professionals, medical students and university students [5]. However, the number of studies with the application of scales, such as Attitudes Toward Obese Persons Scale (ATOP), on morbid obese patients are limited. Attitudes Toward Obese Persons Scale is used to evaluate whether people have favorable attitudes against obese patients or not [5]. Within this study, we wanted to examine the attitudes towards obese people through the eyes of morbid obese patients using ATOP.

METHODS

Between October 2019 - April 2020, 70 (77.8%) female and 20 (22.2%) male, a total of 90 morbid obese patients, who were admitted to the general surgery department to be evaluated for bariatric surgery were included in this study. Local ethics committee approval was obtained prior to this study (2019/08-10). Patients with body mass index (BMI) greater than 40 kg/m^2 were regarded as morbid obese, and patients with BMI greater than 50 kg/m^2 were regarded as severe morbid obese [6]. These 90 morbid obese patients were asked to fill out ATOP, which included 20 statements. Each statement was valued between -3 to +3 points [7].

The participants were asked to mark each statement according to how much they agreed or disagreed with it, using a scale between, -3 to +3 points (-3: I strongly disagree, -2: I moderately disagree, -1: I slightly disagree, +1: I slightly agree, +2: I moderately agree, +3: I strongly agree).

These twenty statements are:
1. Obese people are as happy as nonobese people.
2. Most obese people feel that they are not as good as other people.
3. Most obese people are more self-conscious than other people.
4. Obese workers cannot be as successful as other workers.
5. Most nonobese people would not want to marry anyone who is obese.
6. Severely obese people are usually untidy.
7. Obese people are usually sociable.
8. Most obese people are not dissatisfied with themselves.
9. Obese people are just as self-confident as other people.
10. Most people feel uncomfortable when they associate with obese people.
11. Obese people are often less aggressive than nonobese people.
12. Most obese people have different personalities than nonobese people.
13. Very few obese people are ashamed of their weight.
14. Most obese people resent normal weight people.
15. Obese people are more emotional than nonobese people.
16. Obese people should not expect to lead normal lives.
17. Obese people are just as healthy as nonobese people.
18. Obese people are just as sexually attractive as nonobese people.
19. Obese people tend to have family problems.
20. One of the worst things that could happen to a person would be for him to become obese.

All of these statements were responded by the participants by the help of ATOP scale. In ATOP, points given to each statement by the participant are summed up. This final number is added to 60 in order to reach a total score, which varies between 0-120 [8].

Statistical analysis was performed using the SPSS 20.0 statistical package programme. Numerical variables were stated as the mean (±) standard deviation and medians (minimum–maximum). Categorical variables were stated as percentages. The Mann Whitney U test and independent samples t test were used to compare differences between two groups. The p-value <0.05 was considered significant.

RESULTS

This study included 90 – 70 female (77.8%) and 20 male (22.2%) – morbid obese patients. The mean age of the patients was 36.26±10.28 years (range: 18-65). The mean age of female patients was 36.77±10.22 years (range: 18-65), while the mean age of male patients was 34.50±10.54 years (range: 21-51). The mean BMI of the patients was 45.83±5.70 kg/m^2 (range: 40-65.3). The mean BMI of the female patients was 45.54±5.34 kg/m^2 (range: 40-64.3), while the mean BMI of the male patients was 46.84±6.86 kg/m^2 (range: 40-65.3) (p=0.57). The mean ATOP score of all morbid obese patients was 63.44±18.58 (range: 19-116). The mean ATOP score of female patients was 63.47±20.34 (range: 19-116), whereas the mean ATOP score of male patients was 63.35±10.69 (range: 43-80) (p=0.98). The responses of the patients to the statements within ATOP are depicted are in Tables 1, 2, 3.

The frequency of the responses given by the male and female patients to the third statement pointed out a statistically significant difference (p=0.02). Nevertheless, the frequency of the responses of the patients to the rest of the statements did not show any statistically significant difference (s1:p=0.95, s2:p=0.58, s4:p=0.40, s5:p=0.08, s6:p=0.38, s7:p=0.11, s8:p=0.40, s9:p=0.59, s10:p=0.98, s11:p=0.50, s12:p=0.68, s13:p=0.33, s14:p=0.97, s15:p=0.69, s16:p=0.44, s17:p=0.48, s18:p=0.66, s19:p=0.28, s20:p=0.73. s: statement)

Statement 1 was given -3 points by 42 (46.7%), -2 points by 4 (4.4%), -1 point by 8 (8.9%), 1 point by 11 (12.2%), 2 points by 9 (10%) and 3 points by 16 (17.8%) patients, respectively. The majority of morbid obese patients (60%) did not agree with the statement that obese people were as happy as non-obese people.

Statement 2 was given -3 points by 7 (7.8%) , -2 points by 6 (6.7%), -1 point by 8 (8.9%), 1 point by 10 (11.1%), 2 points by 12 (13.3%), 3 points by 47 (52.2%) patients, respectively. 76.6% of morbid obese patients agreed with the statement that most obese peopl felt that they were not as good as other people.

Table 1: Points given by the patients to the statements within attitudes toward obese persons scale. 60 (66.7%) patients strongly disagreed and 4 (4.4%) patients strongly agreed with the 8th statement, which was “most obese people are not dissatisfied with themselves”. In addition, most patients (58.9%) strongly disagreed with the 17th statement, which was “obese people are just as healthy as nonobese people” while only 7.8% of the morbid obese patients stated that they strongly agreed with this statement.

Score	-3	-2	-1	1	2	3
Statement	**Patients n (%)**					
S-1	42 (46.7%)	4 (4.4%)	8 (8.9%)	11 (12.2%)	9 (10%)	16 (17.8%)
S-2	7 (7.8%)	6 (6.7%)	8 (8.9%)	10 (11.1%)	12 (13.3%)	47 (52.2%)
S-3	17 (18.9%)	7 (7.8%)	3 (3.3%)	8 (8.9%)	10 (11.1%)	45 (50%)

Statement 3 was given -3 points by 17 (18.9%) , -2 points by 7 (7.8%), -1 point by 3 (3.3%), 1 point by 8 (8.9%), 2 points by 10 (11.1%), 3 points by 45 (50%) patients, respectively. 70% of morbid obese patients agreed that most obese people were more self-conscious than other people.

Statement 4 was given -3 points by 28 (31.1%), -2 points by 5 (5.6%), -2 points by 6 (6.7%), 1 point by 9 (10%), 2 points by 13 (14.4%) and 3 points by 29 (32.2%) patients, respectively. 56.6% of morbid obese patients belived that obese workers could not be as successful as other workers.

Statement 5 was given -3 points by 13 (14.4%), -2 points by 5 (5.6%), -1 point by 10 (11.1%), 1 point by 6 (6.7%), 2 points by 21 (23.3%), 3 points by 35 (38.9%) patients, respectively. The majority of the morbid obese patients (68.9%) thought that most non-obese people would not want to marry anyone who was obese.

Statement 6 was given -3 points by 17 (18.9%), -2 points by 8 (8.9%), -1 point by 7 (7.8%), 1 point by 14 (15.6%), 2 points by 20 (22.2%) and 3 points by 24 (26.7%), respectively. The majority of the morbid obese patients (64.5%) believed that severely obese people were usually untidy.

Statement 7 was given -3 points by 19 (21.1%), -2 points by 14 (15.6%), -1 point by 11 (12.2%), 1 point by 21 (23.3%), 2 points by 15 (16.7%) and 3 points by 10 (11.1%) patients, respectively. These results revealed that tendency of morbid obese patients was towards thinking that obese people were usually sociable (51.1%).

Statement 8 was given -3 points by 60 (66.7%), -2 points by 12(13.3%), -1 point by 5(5.6%), 1 point by 3(3.3%), 2 points by 6(6.7%) and 3 points by 4(4.4%) patients, respetively. 85.6% of morbid obese patients strongly disagreed with the statement that “most obese people are not dissatisfied with themselves”.

Table 2: Points given by the female patients to the statements within attitudes toward obese persons scale. 57.1% of the female patients strongly agreed with the 3rd statement, which was “most obese people are more self-conscious than other people”, while only 15.7% of them stated that they strongly disagreed with this statement.

S-20	9 (12.9%)	5 (7.1%)	5 (7.1%)	9 (12.9%)	11 (15.7%)	31 (44.3%)

Statement 9 was given -3 points by 25(27.8%), -2 points by 9(10%), -1 point by 11(12.2%), 1 point by 14(15.6%), 2 points by 12(13.3%) and 3 points by 19(21.1%) patients, respectively. According to these results, half of the morbid obese agreed with the view that obese people were just as self-confident as other people, while the other half of morbid obese patients did not.

Statement 10 was given -3 points by 18(20%), -2 points by 13(14.4%), -1 point by 15(16.7%), 1 point by 12(13.3%), 2 points by 15(16.7%), 3 points by 17(18.9%) patients, respectively. As a result, 50% of the morbid obese patients were in favor of the statement that most people felt uncomfortable when they associated with obese people, while the other 50% disagreed with this statement.

Statement 11 was given -3 points by 20 (22.2%), -2 points by 9 (10%), -1 point by 11 (12.2%), 1 point by 15 (16.7%), 2 points by 14 (15.6%) and 3 points by 21 (23.3%) patients, respectively. 40 patients (44.4%) disagreed while 50 patients (55.6%) agreed with the statement that obese peopole were often less aggressive than non-obese people.

Statement 12 was given -3 points by 12(13.3%), -2 points by 14(15.6%), -1 points by 15(16.7%), 1 point by 19(21.1%), 2 points by 8(8.9%) and 3 points by 22(24.4%) patients, respectively. The majority of the morbid obese patients (54.4%) indicated that most obese people had different personalities than non-obese people.

Statement 13 was given -3 points by 24(26.7%), -2 points by 9(10%), -1 point by 7(7.8%), 1 point by 9(10%), 2 points by 6(6.7%) and 3 points by 35(38.9%), respectively. According to these scores, 50 (55.6%) morbid obese patients had a positive tendency toward the statement that very few obese people were ashamed of their weight.

Table 3: Points given by the male patients to the statements within attitudes toward obese persons scale. Most of the male patients (30%) strongly disagreed with the 3rd statement, which was “most obese people are more self-conscious than other people”. Statistically significant difference was observed between the frequency of the responses given by the male and female patients to the third statement (p=0.02).

S-19	5 (25%)	3 (15%)	3 (15%)	1 (5%)	4 (20%)	4 (20%)
S-20	3 (15%)	0 (0%)	2 (10%)	5 (25%)	2 (10%)	8 (40%)

Statement 14 was given -3 points by 11(12.2%), -2 points by 9(10%), -1 point by 6(6.7%), 1 point by 11(12.2%), 2 points by 12(13.3%), 3 points by 41(45.6) patients, respectively. Majority of the morbid obese patients (71.1%) accepted that most obese people resented normal weight people.

Statement 15 was given -3 points by 7(7.8%), -2 points by 3(3.3%), -1 point by 3(3.3%), 1 point by 17(18.9%), 2 points by 15(16.7%) and 3 points by 45(50%) patients, respectively. The vast majority of the morbid obese patients (80.6%) shared the idea that obese people were more emotional than non-obese people.

Statement 16 was given -3 points by 27(30%), -2 points by 8(8.9%), -1 point by 9(40%), 1 point by 8(8.9%), 2 points by 14(15.6%) and 3 points by 24(26.7%) patients. The vast majority of the morbid obese patients (78.9%) did not agree with the statement that obese people should not expect to lead normal lives.

Statement 17 was given -3 points by 53 patients by 53(58.9%), -2 points by 3(3.3%), -1 point by 11(12.2%), 1 point by 10(11.1%), 2 points by 6(6.7%) and 3 points by 7(7.8%) patients. 74.4% of the morbid obese patients did not agree with the statement that obese people were just as healthy as non-obese people.

Statement 18 was given -3 points by 47(52.2%), -2 points by 12(13.3%), -1 point by 10(11.1%), 1 point by 9(10%), 2 points by 3(3.3%) and 3 points by 9(10%) patients, respectively. 76.6% of morbid obese patients did not agree with the statement that obese people were just as sexually attractive as non-obese people.

Statement 19 was given -3 points by 16(17.8%), -2 points by 15(16.7%), -1 point by 12(13.3%), 1 point by 7(7.8%), 2 points by 11(12.2%), and 3 points by 29(32.2%) patients, respectively. 52.2% of the morbid obese patients agreed with the statement that obese people tended to have family problems.

Statement 20 was given -3 points by 12(13.3%), -2 points by

5(5.6%), -1 point by 7(7.8%), 1 point by 14(15.6%), 2 points by 13(14.4%) and 3 points by 39(43.3%). 58.9% of the patients agreed with the statement that becoming obese would be one of the worst things that could happen to a person.

DISCUSSIONS

Hereditary, social, economic and environmental factors have been included in the etiology of obesity [9, 10]. In accordance with increased obesity rates, bias about obese people has become more prevalent [11, 12]. Negative attitudes toward obese people which lead to prejudice and discrimination have a detrimental impact on the mental health of obese individuals (9). Obese people may experience discrimination in various aspects of life such as work, education and medical care [13-22].

In order to evaluate attitudes toward obese people, ATOP scale has been used in several studies [5]. However, ATOP scale which was used on different populations revealed conflicting results. Puhl et al. compared ATOP scores between female obese patients with and without binge eating disorder. The mean ATOP scores were similar in both groups. Puhl et a. suggested that obesity increased vulnerability to negative weight-based attitudes regardless of eating disorder [8]. Kadar et al. reported that obesity bias was common in chiropractic students and faculty members. Students and faculty members had anti-obesity attitudes according to ATOP. In addition, ATOP scores did not show significant difference between preclinical and clinical students [23]. Soto et al. reported more positive attitudes toward obese individuals in psychology students compared to medical students. Moreover, positive attitudes of the students according to ATOP were correlated with frequent contact with obese people [24]. Darling et al. investigated attitudes toward obese people in graduate and undergraduate nursing students, graduate education and graduate social work students. Darling et al. reported worse attitudes in nursing students, younger participants and participants without an obese family member or a friend [5]. Ambwani et al. reported that 92.5% of young adults aged 18 to 29 approved at least one negative attitude within ATOP. However, approval of negative attitudes did not show significant difference according to BMI [11].

It has been suggested that negative attitudes toward obese people might be observed in women more commonly than in men. However, Glenn et al. reported that women were significantly more positive in their attitude toward obese people compared to men [25]. On the other hand, Darling et al. reported similar ATOP scores in females and males, thus no gender difference in the attitudes toward obese individuals was identified [5]. Moreover, several studies revealed that individuals who had a relative or a friend with obesity or had contact to obese people commonly tended to have more positive attitudes toward obese people [5, 24, 26]. However, attitudes of obese people toward other obese people have not been investigated in depth, yet.

Since the ATOP score ranges from 0 to 120 and higher scores reveal more positive attitudes, the mean ATOP score of our patients (63.44±18.58) which was slightly higher than midpoint indicated that morbid obese had positive attitudes toward obese people. Previous studies reported the mean ATOP score was 60 in obese women, whereas 59.6 in obese women with binge eating disorder [8], 57.6 in preclinical chiropractic students, 59.7 in clinical chiropractic students, 49 in preclinical faculty members, 52.2 in clinical faculty members [8] and 68.5 in nursing students, 77.3 in social work students, 71.4 in graduate education students [5].

Within this study, the majority of the patients (77.8%) admitted to the general surgery clinic for bariatric surgery evalution were female. This result may point out two different findings. First of all, obesity is more common in female than male individuals. Secondly, the number of obese women seeking medical help to fight against obesity is more than the number of male patients. Within this study, no significant difference was observed in mean ATOP scores of the female and male morbid obese patients (p=0.98). Therefore, our results revealed that both women and men with morbid obesity had similar attitudes toward obese people. However, points given by morbid obese patients to the 3rd statement ‘’Most obese people are more self-conscious than other people’’ showed gender difference. More than half of female morbid obese patients (57.1%) stated that they strongly agreed to the 3rd statement while most of the male morbid obese patients (30%) stated that they strongly disagreed to the same statement. This result might reveal that morbid obesity might affect female and male patients differently in building relationship or in communicating with other people. Thefore, novel and gender specific scales about obesity may be helpful in evaluating obese patients before making an appropriate treatment plan prior to bariatric surgery.

Moreover, with the help of ATOP applied on morbid obese patients, we have gained insight into the attitudes of morbid obese patients on obese individuals. In addition, we had the opportunity to evaluate obesity from the perspective of morbid obese patients. Unfortunately, 60% of morbid obese patients did not feel as happy as non-obese people. 74.4% of the morbid obese patients thought that obese people were not as healthy as non-obese people. Moreover, 76.6% of morbid obese patients replied that obese people were not as sexually attractive as non-obese people. Nevertheless, 80.6% of morbid obese patients shared the idea that obese people were more emotional than non-obese people.

In conclusion, ATOP has been investigated in various studies in order to determine whether non-obese individuals had negative attitudes toward obese individuals or not. However, the data are scarce in the English medical literature about the attitudes of morbid obese patients toward obese individuals. Thefore, we evaluated ATOP in morbid obese individuals to gain a sight whether morbid obese patients had negative perceptions about other obese people. Any ATOP score above the midpoint, which is 60 points, has been reported to indicate that the individual had positive attitudes toward obese people [27, 28]. However, higher scores than 60 indicate more positive attitudes toward obese individuals. Therefore, ATOP scores identified within our study which were slightly higher than 60 in both our female and male patients indicated that morbid obese patients had neither negative nor highly positive attitudes toward obese people.

Evaluation of systemic second-line therapy in recurrent or metastatic esophageal cancer

Xenia E. Bacinschi[1,3], Anca Zgura[1,3], Monica I. Stănuică[4], Laura Iliescu[2,3], Rodica M. Anghel[1,3]

Abstract: *Background: More than half of patients with locally advanced esophageal cancer are unresponsive to first-line chemotherapy. To date, there is no standard second-line regimen; new agents, such as immune-checkpoint inhibitors or anti-Neurotrophic Tropomyosin-Related Kinas agents, have only been recently recommended. This study aimed to assess the benefits of classical second-line chemotherapy in terms of survival and tolerance. Materials and Methods: This retrospective analysis assessed the benefits and tolerance of different second-line regimens of chemotherapy in progressive, locally advanced or metastatic oesophageal cancer treated at the department of Radiotherapy-Oncology at the Institute of Oncology between January 2011 and January 2017. Results: The analysis found 87 patient files with a median age 59.5 years (ranging between 41 and 84), of which 40.2% (35 patients) failed the first-line platinum and 5-fluorouracil combination. Histology favoured adenocarcinomas (63.2%). The patients were in good clinical condition, with ECOG 0–1 in 86.1% (74 patients), and less than five percent had more than three metastatic sites (3.4%, 3 patients). The regimens were mostly two-drug cytotoxic (53.9%, 47 patients): FOLFIRI in 18 patients (20.7%), FOLFOX in 18 patients (20.7%), vinorelbine–platinum combination in 11 patients (12.6%), and docetaxel in 40 patients (38.7%). The median treatment duration was 7.74 weeks (range 1 to 12). The general response rate was 47.1% (41 patients), including stable disease. The median time to progression was 7.61 weeks, with a range between 1.6 and 8.6 weeks, with no differences in this respect among the fourth type of treatment received (p = 0.170). Grade 3–4 toxicities, including neutropenia, gastrointestinal problems, and metabolic disorders, were observed in 44 patients (50.6%). The median event-free survival was 2 months (range between 1 and 6.3), and 63.2% (55 patients) subsequently received a third line of chemotherapy. Conclusion: Second-line chemotherapy is still the first-choice recommendation in all fit patients with advanced oesophageal cancer. The new agents are efficacious only in cases with PD-L1 positive or high microsatellite instability.*

Keywords: *second-line chemotherapy, locally advanced/metastatic oesophageal cancer, survival benefit, toxicity*

INTRODUCTION

Esophageal cancer has two histopathological subtypes: squamous carcinoma found in the superior and upper-two-thirds regions [1], and adenocarcinoma, which develops at deep inferior and junctional mucosal glands. Both have high similarities in their pattern of metastasis [2]. Esophageal cancer is the sixth most common cause of specific deaths worldwide [3]. The peak of incidence is reported in the sixth decade of age, and cancer occurs more frequently in men [4].

Approximatively half of the patients have advanced disease at diagnosis. Three-quarters of resectable disease will relapse, of which more than half will be candidates for

second-line systemic therapy [5]. Overall five-year survival is less than 10% [3].

Regarding the first line, for adenocarcinoma, the regimen used is similar to those used in gastric cancer, fluoropyrimidine-based chemotherapy while in squamous esophageal cancer the regimen is cisplatin-based and in general, regardless the histology, the median overall survival (OS) does not exceed nine months [6].

Currently, there is no established second-line systemic treatment for esophageal cancer [7]. Subsequent lines of chemotherapy have recently been proposed by NCCN (National Comprehensive Cancer Network) guidelines for locally advanced or metastatic esophageal and oesophagogastric junction cancer [8]. New treatment options include ramucirumab and paclitaxel which give a 2-month benefit in median overall survival (9.6 months versus 7.4 months for paclitaxel only, p = 0.017) [9]. Pembrolizumab is a category 1 recommendation anti-PD1 (programmed cell death protein) antibody for esophageal PD-L1 (programmed death-ligand 1) positive or for any histology displaying MSI-H (microsatellite instability-high) or d-MMR (deficient mismatch repair) status [8] based on a benefit of 1 month (8.2 vs. 7.1 months, HR = 0.78, P = 0.0095) versus classical chemotherapy taxanes or irinotecan in the squamous cell carcinoma subgroup [10]. With a 2B level of recommendation, entreticnib is proposed for a median 10 months' duration of response, 95% CI [7.1 - NE] [11], and larotrectinib is proposed in NTRK (Neurotrophic Tropomyosin-Related Kinase) fusion-positive esophageal tumours [12].

MATERIALS AND METHODS

Medical files from the institutional database of patients diagnosed with metastatic invasive esophageal squamous cell carcinoma (SCC) or adenocarcinoma (AC), referred to our institution for second-line chemotherapy were analysed. The main inclusion criteria were age >18 years, clinical-stage IV according to AJCC 8th edition [15], treatment by at least one regimen of chemotherapy or radiotherapy and assessed for response.

Patients were excluded if they were eligible for salvage surgery or had synchronous cancer or severe comorbidities that might impair our results. The study was approved by Ethycal Committee of Insitute of Oncology "Prof. Dr. Alexandru Trestioreanu", Bucharest, Romania no 1597/17th December 2010.

The primary outcome was time to progression, evaluated between the start of second-line chemotherapy and first progression or death by any cause. Secondarily, treatment benefit was evaluated using CT scan, and, in terms of tolerance, the rate and duration of grade III-IV adverse events (AE) classified according to CTCAE v. 4.03 [16].

Data were analysed using SPPS version 23 (IBM Corporation, Armonk, NY, USA). Non-parametric tests were used to compare subgroups. The chi-squared test determined the correlation between response to treatment and demographic and clinical variables. Fisher's exact test was employed when there were fewer than five cases in any cell of the 2×2 table. The associations between variables and survival parameters were analysed by logistic regression analysis, and survival curves were generated using the Kaplan–Meier method and compared using the log-rank test. Hazard ratio (HR) and 95% confidence interval (CI) for variables were calculated using the Cox proportional hazard model. All statistical tests were two-sided, and a p-value < 0.05 was considered significant.

RESULTS

3.1. Patient characteristics

During the period of analysis, a total of 87 patients were treated in our department by chemotherapy for esophageal cancer, with a mean age 59.5 (range between 41 and 84). Among them, 37 patients were treated for recurrent disease, 29 patients had metastatic disease at initial presentation, and 21 patients received the second-line treatment for a locally advanced disease with no indication of surgery or radiotherapy.

The principal histology was adenocarcinoma (63.2%, 55 patients), and the primary lesion was typically situated in the lower and junction of the esophagus (48.9%, 51 patients). One-third of patients had liver metastasis, but almost all had no more than two sites of secondary lesions (96.6%, 84 patients) and were in generally good condition, with ECOG 0–1 in 85.1% (74 patients) (Table 1).

Table 1: Patients characteristics in target population

Characteristics	n	%
Age (years): median 59.5; range [41–84]

Abbreviations: CHT = chemotherapy, ECOG = Eastern Cooperative Oncology Group Performance Status, FU-Pl: 5-fluorouracil–platinum regimen, LV5FU2CDDP =5-fluorouracil 1600 mg/m2 + leucovorin 200 mg/m2 + cisplatin 50 mg/m2q2w, 5FU-CDDP=5-fluorouracil 1000 mg/m^2 day 1-4 + cisplatin 100 mg/m^2 day 1 q3w, PR = partial remission , PD = progressive disease, SD = stable disease.

3.2. Treatment characteristics

The first-line combination of cisplatin plus 5-FU (5-fluorouracil) was most typical in localized and metastatic esophageal cancer (40.2%, 35 patients). This combination involves 5-fluorouracil 1000 mg/m^2 per day for 4 days and cisplatin 100 mg/m^2 on day 1 every 21 days (17) or, in the so-called LV5-FU2 – cisplatin two-week regimen, cisplatin 50 mg/m^2, calcium folinate 200 mg/m^2, 5-FU 400 mg/m^2 on day 1 and 5-FU 1200 mg/m^2 over a 46-hour continuous infusion (18). Other protocols used were FOLFIRI (39 pts, 44.8%) vinorelbine-cisplatine based (10 pts, 11.5%) and taxane based (3 pts, 3.4%).

Patients who received FOLFOX regimen, as second line treatment modified they represented 20.7% (18 patients), 46% (40 patients) received a docetaxel regimen, 20.7% (18 patients) received a FOLFIRI regimen, and 12.6% (11 patients) received a vinorelbine–cisplatin regimen. Details regarding the protocols used in second line are listed in the Table 2.

Table 2: Second line chemotherapy protocols summary.

Second line regimen	Protocol summary	Number patients	Response rate	Reference
FOLFOX6	oxaliplatin 85 mg/m^2, leucovorin 200 mg/m^2, 5-FU push 400 mg/m^2, 5FU 2400 mg/m^2 for 46 hours, q2w	18 (20.7%)	83.3% (15 pts)	(19)
NVB-CDDP	vinorelbine 25 mg/m^2 day 1+ 8, cisplatin 80 mg/m^2 q3w	11 (12.6)	45.5% (5 pts)	(20)
FOLFIRI	irinotecan 150–180 mg/m^2, 5-FU 400 mg/m^2 push, leucovorin/ calcium folinate acid, 125mg/m^2, 5-FU 2400 mg/m^2/46 hours, q2w	18 (20.7%)	50% (9 pts)	(21)
DTX	docetaxel 75mg/m^2, q3w	40 (46%)	12 (30%)	(22)

Abbreviations: FOLFOX6 = Oxaliplatin 85 mg/m^2+ leucovorin 200 mg/m^2 + 5 FU 2800 mg/m^2 q2w, FOLFIRI = Irinotecan 150–180 mg/m^2 + leucovorin 125 mg/m^2 + 5-FU 1600 mg/m^2 q2w, NVB-CDDP = Vinorelbine 25 mg/m^2 day 1 + 8 + cisplatin 80mg/m^2 q3w, DTX = docetaxel 75 mg/m^2 q3w.

The median time of chemotherapy was 7.74 weeks, with a range between one and twelve weeks. The mean number of cycles was 2.36, with a range between one and seven cycles and no significant differences was registered between the medians of any regimen ($p = 0.065$). Choice of chemotherapy regimen was correlated with the initial stage of disease, histological subtype, the number of metastatic sites, site of metastasis and performance status ($p < 0.0001$). More than half of the patients included in the study were able to benefit from the third line of treatment (55 pts, 63.2%) (Table 3).

3.3. Benefit

The response rates that were obtained were as follows: 28.7% (25 patients) had partial remission, 18.4% (16 patients) stable disease and 52.9% (46 patients) recorded either clinical or radiological progression.

Table 3: Second line chemotherapy protocols characteristics and toxicity.

Characteristics	n	%
Number of cycles: median 2.87, range [1–7]		
< 2	28	32.2
2–4	45	51.7
> 4	14	16.1
CHT duration (weeks): median 7.74, range [1–12]		
< 6	20	22.9
6–8	52	59.7
> 8	15	17.3
Grade 3–4 toxicities		
Without	44	50.6
Haematological	30	34.5
Gastrointestinal	10	11.5
Metabolic disorders	3	3.4

The difference between the response to different second line regimen of chemotherapy were not statistically significant (p=0.042).

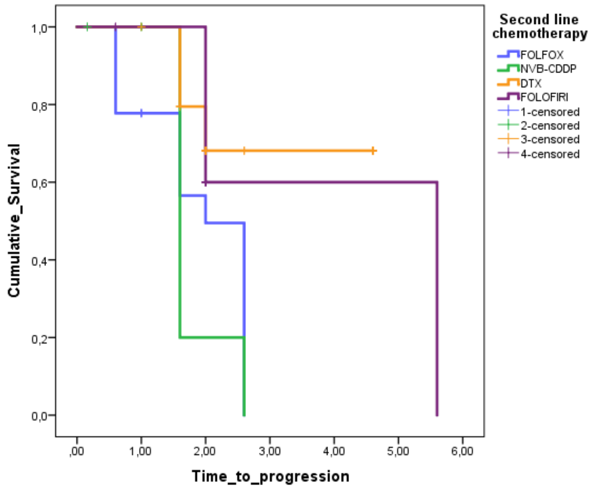
We estimated that the median OS on the basis of the results of several studies of second-line chemotherapy [26-29].

Response was directly correlated with primary tumour location (p = 0.022) and histopathological subtype (p = 0.017) and with tumour burden and type of chemotherapy regimen (p < 0.0001).

The median time to progression was 7.61 weeks, ranging between 1.6 and 8.6 weeks, with no statistical difference between the fourth type of treatment received (p = 0.170).

Time to progression was associated with the number of metastatic sites (HR 2.886, p = 0.004) but not with the type of chemotherapy regimen (p = 0.373). By contrast, the log-rank test showed significant differences in time to progression by type of chemotherapy (chi-square 22.1852, p < 0.0001) (Figure 1).

Figure 1: Kaplan–Meier curves in locally advanced or metastatic oesophageal cancer patients according to the second-line chemotherapy regimen.



Fifty-five patients (63.2%) could benefit from a subsequent, third line of chemotherapy.

The median event-free survival for all patients was two months, with a range between 1 and 6.3 months.

3.4 Toxicity

Forty-four patients (50.6%) displayed no grade III-IV toxicities. Seven patients displayed haematological and gastrointestinal disorder together, and all patients presenting metabolic disorder also had febrile neutropenia.

DISCUSSION

Esophageal cancer are a challenging disease for which there are limited treatment effective options. Despite research, the only treatment with clinical benefit and more accessible in the second-line setting remains chemotherapy.

The population in our study was in relatively good clinical condition: 85.1% with ECOG 0 or 1, almost all without more than two sites of metastasis (96.6%), younger than 70 and, in more than 60%, bearing adenocarcinoma as histological subtype. In this analysis, the most-used (53.9% of cases, 47 patients) were two-agent regimens: FOLFIRI, or cisplatin–vinorelbine, and FOLFOX. The median treatment duration was 7.74 weeks, and most had received 5-fluoropyrimidine in the first line (85.1%, 74 patients).

The general benefit was reflected by a 47.1% (41 patients) response rate, including cases with disease stabilisation, the median time to progression of 7.61 weeks (range 1.6 to 5.6 weeks) and a median time to death of 2 months (range 1 to 6.3 months). Chemotherapy was generally tolerated, though almost half of patients developed grade III-IV toxicities; one-third of these were mostly non-complicated grade III anaemia or thrombopenia.

Several earlier retrospective or phase II studies have evaluated whether second-line chemotherapy might be useful for oesophageal cancer patients.

Regarding irinotecan, in a small phase II study, 29 patients (27 with adenocarcinoma) were given capecitabine 2,000 mg/m2 day on days 1–14 and irinotecan 250 mg/m2 every 3-week cycle. The study showed an objective response of 17% (five patients) and median progression-free survival of 3.1 months 95% CI [2.2–4.1] and median OS of 6.5 months 95% CI [6–7.1] with a 10% rate of febrile neutropenia [24].

In another phase II study, irinotecan combined with cetuximab in 63 cases of platinum-refractory gastro-esophageal carcinoma, led to an 11% (6 patients) partial response rate and 37% (23 patients) rate of stabilization, with median progression-free survival of 2.8 months, median overall survival of 7.1 months and a 32% rate of grade III-IV toxicities [25].

Even as a single agent, irinotecan showed a survival advantage, compared to best supportive care, in 40 patients with metastatic or locally advanced adenocarcinoma gastro-esophageal of the junction. Irinotecan given of 250 mg/m2 with the possibility of an increase to 350 mg/m2 if well-tolerated, gave a 53% rate of stable disease and 50% clinical benefit versus 7% and a median survival of 4 months 95% CI (3.6–7.5) versus 2.4 months 95% CI (1.7–4.9) and 0.48 HR for death 95% CI (0.25-0.92) [26].

In untreated metastatic gastro-esophageal adenocarcinoma (N = 220 patients), by substituting oxaliplatin for cisplatin in a FOLFOX-like regimen (fluorouracil 2,600 mg/m^2 over 24-hour infusion, leucovorin 200 mg/m^2 and oxaliplatin 85 mg/m^2 every 2 weeks) there was no statistically difference in terms of progression-free survival (5.7 vs. 3.9 months, p = 0.077), response rate (35% versus 20%) or median overall survival (10.7 vs. 9.8 months). Adverse events were significantly fewer (9% vs. 19%) and treatment showed better responses in patients aged over 65 years old compared to cisplatin: 41.3% response rate versus 16.7% (p = 0.012), time to treatment failure of 5.4 versus 2.3 months (p < 0.001) and progression-free survival of 6.0 versus 3.1 months (p = 0.029) [19]. A later meta-analysis (N =1294 patients in three randomized trials), regarding the meme subject, showed improved progression-free survival (HR = 0.88, p = 0.02) and overall survival (HR 0.88, p = 0.04) in advanced, unresectable gastric cancer [27].

In a monocentric retrospective study of 94 patients with metastatic esophageal cancer, a modified FOLFOX 6 regimen comprising fluorouracil 2400 mg/m^2 over 48 hours after a bolus of 400 mg/m^2, leucovorin 400 mg/m^2 and oxaliplatin 85 mg/m^2 gave an objective response rate of 41.4% (39 patients), of whom 6.3% (6 patients) with a complete response and 21.3% (20 patients) with stable disease. Any grade of hematologic toxicity was found in 69.1% of cases [28].

Regarding taxane-based chemotherapy, the UK COUGAR-2 phase III study(N=168) confirmed the benefit of second-line chemotherapy by docetaxel 75 mg/m^2 every 3 weeks compared to best supportive care by a median OS of 5.2 versus 3.6 months (HR 0.67, 95% CI [0.49–0.92]; p = 0.01) in patients with a good performance status [22].

In a retrospective study which assessed in 163 patients the clinical benefit of second-line taxane therapies, docetaxel at 70 mg/m^2 every 3 weeks versus paclitaxel 100 mg/m^2 weekly for 6 weeks of 8 weeks cycle, survival without progression was identical (2.3 months) for both regimens the overall survival was 6.1 versus 5.3 months, with 32.6% and 16.1% rates, respectively, of grade III-IV toxicities [29].

Only a few randomized studies have compared the benefits of different second-line chemotherapy regimens, mainly in gastric cancer and in Asian patients.

In 202 Korean patients with less than two prior lines of chemotherapy, randomized in a 2:1 ratio treated with docetaxel or irinotecan compared with supportive treatment,was recorded a superior overall survival (5.3 vs. 3.8 months; HR 0.66, p = 0.007) while no survival difference was recorded between docetaxel and irinotecan. The tolerance was good, the hematologic toxicities manageable and the rates of non-haematologic toxicities were comparable in both groups but there was with no significant differences in terms of survival between two regimens of chemotherapy [30].

In another Asian study, in 223 Japanese patients randomized to received paclitaxel alone or irinotecan alone as second line treament, the median overall survival was comparable (9.5 vs. 8.4 months, p = 0.38), although less toxicity appeared in the paclitaxel arm and more of those patients went on to receive third-line chemotherapy [31].

In a meta-analysis of 28 studies (N = 4810 patients), mostly retrospective, the second line showed no difference between taxane- and irinotecan-based regimens in terms of overall survival (HR 0.94, CI [0.78–1.13]) or survival without progression (HR 0.84, CI [0.69–1.03]), nor was there any difference for any single-agent regimen compared to best supportive care (HR 0.65, 95% CI [0.53–0.79]. Median survival gain ranged from 1.4 to 2.7 months among the individual studies considered. Doublet chemotherapy based on taxane or irinotecan plus platinum and fluoropyrimidine did not display different survival but showed increased toxicity compared to taxane or irinotecan monotherapy [6].

As far as new agents, despite the failures of several clinical trials involving molecularly targeted agents, several have shown some benefits worth mentioning that represent the basis of NCCN recommendations [8].

Ramucirumab, an antibody that targets the vascular endothelial growth factor receptor 2, the expression of which might be a mechanism of the aggressiveness of gastric and gastro-esophageal junction adenocarcinoma, led in pre-treated patients with esophagogastric cancer significant survival benefit, 5.8 months compared with 3.8 months for placebo (HR 0.776, 95% CI [0.603–0.998]), a similar benefit were seen in the COUGAR-02 trial assessing the benefit of docetaxel [32].

By adding paclitaxel to ramucirumab, in another phase III trial, it was reported a significant benefit in terms of median OS 9.6 months versus 7.4 months, HR 0.807, 95% CI [0.678–0.962] (p = 0.017). In terms of adverse events, the association was mainly marked by hypertension (14%, 46 patients vs. 2%, 8 patients), fatigue (12%, 39 patients vs. 5%, 18 patients) and abdominal pain (6%, 20 patients vs. 3%, 11 patients) [9].

Regarding the role of immune checkpoint inhibitors, in the KEYNOTE 181 trial (N = 628 patients), the response rates with pembrolizumab were double or even triple those achieved with chemotherapy at the investigator’s choice (paclitaxel, docetaxel, or irinotecan), though the median duration of response was longer in the group with PD-L1 CPS (Combined Positive Score) equal or higher than 10 (9.3 vs 7.7 months with chemotherapy HR 0.69; 95% CI [0.52–0.93]; $p = 0.0074$); 12-month overall survival rate in CPS ≥10 patients was 43% compared to 20%. With pembrolizumab, fewer patients had drug-related adverse events of any grade (64% vs. 86%) or grades 3 to 5 (18% vs. 41%) compared with chemotherapy. The most common events were fatigue (11.8%), hypothyroidism (10.5%), loss of appetite (8.6%), nausea (7.0%) and diarrhoea (5.4%) [10]. The phase III KEYNOTE-590 study (ClinicalTrials.gov identifier NCT03189719), assessing the efficacy and tolerance of pembrolizumab plus chemotherapy as first-line therapy for locally advanced or metastatic esophageal carcinoma, is ongoing [33].

HER 2 (human epidermal growth factor receptor) expression was not considered in the study due to the fact that it was not frequently found in the study population, and Trastuzumab treatment is not approved in Romania for second-line treatment [23, 34].

The time to disease progression was quite difficult to track due to the fact that several patients have continued their treatment at other institutions or have been transferred to a palliative care unit without the possibility to obtain their date of death, because in Romania there is not a computerized death reporting system and this is a limitation of the study.

The limitations of our study were the retrospective character, small number by each subgroup of treatment patients and lack of the subgroup of patients treated with both active and passive immunotherapy.

CONCLUSIONS

Immunotherapy using immune checkpoint inhibitors has revolutionized the cancer treatment and becomes the new standard of second line treatment in non-operable advanced or metastatic esophageal cancer.

Moreover, the new agents seem to be efficacious only in cases where the expression PD-L1 is positive or high microsatellite instability is present.

The old chemotherapy regimen has a similar efficacy and relatively good tolerance and still might the first-choice recommendation in fit patients

This analysis showed a generally good response to systemic treatment, comparable to the responses reported in other studies.

Our study did not show a difference in clinical benefit depending on the treatment regimen.

Moreover, the incidences of adverse events such as grade 3 or higher leukopenia and febrile neutropenia was observed in all patients. Forty-four patients (50.6%) displayed no grade III-IV toxicities. Seven patients displayed haematological and gastrointestinal disorder together.

Evaluation of the accuracy of E-FAST ultrasound in blunt trauma patients referred to the Emergency Department

Hassan Goodarzi[1], Ali N. Timarchi[1], Mohammad Raeeszadeh[1], Sardollah Mahmoodi[1], Hamid R. Javadzadeh[1], Soleyman Heydari[1]

Abstract: *Introduction: Trauma is one of the most common causes of death in the world. E-Fast ultrasound can detect the haemoperitoneum, intravenous pneumothorax, and hemothorax. In this study, we evaluated the accuracy of E-FAST focused ultrasound in blunt trauma patients referred to the Emergency Department.*

Methods: In this study 167 blunt trauma patients were included. E-FAST is performed from four standard spaces in terms of free fluid, chest in terms of hemothorax, and pneumothorax. Ultrasound is performed on the trauma patient and the obtained results were compared with the result of the standard gold CT scan test. All patient information including age, sex, mechanism of trauma, patient ISS, E-FAST result, and CT scan result were registered.

Results: Overall, 174 patients were included that 45 (25.9%) of them were females. The mean age of the patients was 38.39±12.31 years. E-FAST had a sensitivity of 66.7 and a specificity of 100% in the diagnosis of hemothorax. Also, a positive predictive value of 100% and a negative predictive value of 99.4% were detected for 120 people in both normal tests.

Conclusion: The results show E-FAST is a suitable alternative to CT scan in the diagnosis of hemothorax, pneumothorax, and free fluid in the abdomen, vulva, and pericardial cavity. Due to portability, safe body, no need for contrast, fast performance, as well as cheapness, and reproducibility, it will be a great help in diagnosing trauma-related lesions and prompt and timely treatment. CT scan should be used only in limited cases and special indications.

Keywords: *E-Fast ultrasound, blunt trauma, accuracy*

INTRODUCTION

Trauma is one of the most common causes of death in the world. Sometimes due to accompanying trauma and distracting pain, our findings in physical examinations are limited. In trauma patients, internal bleeding is life-threatening and requires prompt and timely action [1-3].

E-Fast ultrasound can detect the haemoperitoneum and intravenous pneumothorax and hemothorax. It can be performed in traumatic patients with symptoms of hemorrhagic shock or evidence of intra-abdominal injury [1]. The features of FAST have led to this practice being adopted as an international standard of care in most developed countries of the world [2].

The benefits of this method can be noninvasive, portable; the low cost can be done in less than 5 minutes, repeatable without the need for radiation and counter, and can be performed by an emergency medicine specialist or surgeon [3-5].

Studies have shown that E-Fast has a sensitivity of between 99-86% compared to other imaging and diagnostic modalities in the presentation of haemoperitoneum [7]. Laparotomy requires early diagnosis to minimize mortality and morbidity, and FAST can also be a reliable surrogate for CT scans in the diagnosis of intra-abdominal fluid [8-13]. The use of CT is limited due to its high cost and its harms.

In this study, we evaluated the accuracy of E-FAST focused ultrasound in blunt trauma patients.

METHODS

The study was performed on 167 blunt trauma patients referred to the three emergency departments of Baqiyatallah, Shohadae 7th Tir and Imam Hussein Hospital. The statistical population was Multiple Traumatic Blunt Patients and referred to those three emergency departments. E-FAST is performed from four standard spaces in terms of free fluid, chest in terms of hemothorax, and pneumothorax. Ultrasound is performed on the patient's bed and the obtained results are compared with the result of the standard gold CT scan test.

All patient information including age, sex, mechanism of trauma, patient ISS, E-FAST result, and CT scan result are entered in the questionnaire form. In this study, patients are examined for the presence of free fluid in the pelvic abdomen, pericardium, and the presence of free fluid in the pleural cavity on both sides. Patients who are admitted to the emergency room as blunt triage trauma, which includes car accident, motor accident, and fall from a height, and a fight, all-penetrating trauma, were excluded from the study. At the beginning of hospitalization and in the primary survey stage, the E-FAST blunt trauma patients were operated on from the pelvic abdomen and chest (Morrison Patch, Splenorenal free fluid around the bladder, pericardium, and pleural cavity on both sides).

Its positive and negative results were recorded in a specific form. All patient characteristics by trauma time, "time of visit", age, sex, "trauma mechanism", are recorded in the patient's specific form and patient records.

ISS under 16 is excluded from the study because they do not need a CT scan. Patients with ISS above 16 are visited by a surgeon after the initial procedures. If the patient is hemodynamically unstable and undergoes laparotomy and thoracotomy without a CT scan, the patient's laparotomy and thoracotomy results are compared with the E-FAST result. For other patients, if they had a CT scan of the abdomen and chest, the results would be recorded in the desired form. Finally, only 176 patients who had a CT scan of the abdomen and chest, or a laparotomy and thoracotomy are included in this study. Their results are compared with the E-FAST result

Data presented as frequency, percent, mean and standard deviation. An Independent T-test was used for comparing data between various levels. Finally, accuracies indices such as sensitivity, specificity, positive and negative predictive values were assessed for determining the accuracy of E-FAST diagnostic value compared to CT scan as a standard gold test. P-value <0.05 was considered significant.

RESULTS

Overall, 174 patients were included that 45 (25.9%) of them were females. The mean age of the patients was 38.39±12.31 years. Among the total number of people, 61 (35.1%) referred to pedestrians due to a vehicle accident. The relationship between gender and the mechanism of trauma was statistically significant (P<0.001) (Table 1).

Table 1: Distribution subject respect to the mechanism of trauma and sex

			Mechanism of trauma						**Total**
			Car accident	**Vehicle accident with pedestrians**	**Car overturning**	**Falling from a height**	**Falling from a motorcycle**	**Conflict**	
Gender	Female	Count	5	29	2	4	5	0	45
		% of Total	2.9%	16.7%	1.1%	2.3%	2.9%	0.0%	25.9%
	Male	Count	24	32	26	13	33	1	129
		% of Total	13.8%	18.4%	14.9%	7.5%	19.0%	0.6%	74.1%
Total		Count	29	61	28	17	38	1	174
		% of Total	16.7%	35.1%	16.1%	9.8%	21.8%	0.6%	100.0%

The mean ISS in all patients was 29.65±10.25. The mean ISS was 28.15±10.93 in females and 30.05±9.99 in males

(P=0.28).

E-FAST showed normalized outcomes in 125 patients (711.8%), 2 patients (1.1%) hemothorax, 4 patients (2.3%) pneumothorax and 18 patients (3.10% morison pouch fluid, 13 cases (7.7%), 5% splenorenal free fluid, 11 cases (3.6%) of free fluid in pelvis.

One case of free fluid in the pericardial was observed that was not confirmed by CT scan. Two patients were diagnosed with hemothorax in both tests and 3 patients were diagnosed with pneumothorax in both tests.

Out of 176 patients, CT-SCAN results for 133 (76.4%) normal, 3 (1.7%) hemothorax, 4 (2.3%) pneumothorax, 31 (17.8%) free fluid in the abdominal and the pelvis, and 3 patients were found to have retroperitoneal fluid (Table 2).

Table 2: Distribution of results according to E-FAST and CT-SCAN tests

		CT.SCAN						Total (%)
		Hemothorax	Pneumothorax	Free fluid in the abdominal and pelvic		Retroperitoneal fluid	Normal	
E-FAST	Hemothorax	2	0	0		0	0	2 (1.1%)
	Pneumothorax	0	3	0		0	1	4 (2.3%)
	Pericardial effusion	0	0	0		0	1	1 (0.6%)
	Morison pouch fluid	0	0	14	31	0	4	18 (10.3%)
	Splenorenal free fluid	0	0	9		0	4	13 (7.5%)
	Free fluid in the pelvic	0	0	8		2	3	11 (6.3%)
	Normal	1	1	3		1	120	125 (71.8%)
Total (%)		3 (1.7%)	4 (2.3%)	31 (17.8%)		3 (1.7%)	133 (76.4%)	174

E-FAST had a sensitivity of 66.7 and a specificity of 100% in the diagnosis of hemothorax. Also, a positive predictive value of 100% and a negative predictive value of 99.4% were detected for 120 people in both normal tests (Table 3).

Table 3: Sensitivity, specificity, positive predictive value, and negative E-FAST predictive value

Items	Sensitivity	Specificity	Positive predict value	Negative predictive value
Hemothorax	66.7%	100%	100%	99.4%
Pneumothorax	75.0%	99.4%	75.0%	99.4%
Normal	90.2%	87.8%	96.0%	73.4%
Free fluid in the abdominal and pelvic	91.1%	88.0%	63.2%	97.7%

DISCUSSION

In this study, 174 patients were included. The mean ISS in all patients was approximately 30 and the mean was not significant in both sexes. The mean ISS indicates the severity of considerable. In this study, E-FAST had a sensitivity of 91% and a specificity of 88% in the diagnosis of normal and normal individuals. E-FAST obtained 66% sensitivity and 100% positive predictive value and 4.99% negative predictive value in the diagnosis of hemothorax. In this study, this test had a sensitivity of 75% and a specificity of 2.99% in the diagnosis of pneumothorax, and a positive predictive value of 74% and a negative predictive value of 4.99% were obtained. Results showed all items are almost equal and even better in some respects. The results indicate that FAST is a very good alternative to CT scan in the diagnosis of hemothorax, pneumothorax, free fluid in the abdomen, vulva, and pericardium. There were several cases of retroperitoneal bleeding that could not be detected by FAST but were detected by CT scan.

In a study by Porter et al. on a large number of patients (2576 patients), FAST achieved a sensitivity of 93% and a specificity of 90% in the diagnosis of hemoperitoneum. In another study by MT.MILLER on 359 patients Sensitivity was 68%, specificity was 98%, positive predictive value was 67% and negative predictive value was 93% in the diagnosis of hemoperitoneum [14].

In another study by Porter et al., It was observed that among 1631 people with abdominal trauma, fast ultrasound is one of the main methods with high sensitivity and specificity. This sonography can discuss the complications of the disease [15].

In another report by McKenney et al., 899 ultrasounds of abdominal trauma were performed, of which 101 were positive and 783 were negative. Among the negative cases, 768 patients were confirmed by CT scan, surgery, and subsequent follow-up. Among the positive cases, 95 patients were confirmed. In this report, 86% sensitivity and 99% specificity were calculated [16].

However, it seems that in our study, due to the high accuracy of E-FAST in intra-abdominal, pelvic, and thoracic lesions in blunt trauma patients, it is recommended that more training be given to emergency medicine students and surgeons by a radiologist. Now it is preferable to use high-quality methods and high resolution and at frequent and regular intervals without hasty action.

Also, if E-FAS are performed at regular intervals (4-6) hours for hemodynamically stable trauma patients, its results will be much better, but its false positive and negative cases will be minimized and its sensitivity will be more than 98. And due to its advantages such as portability, safe body, no need for contrast, fast performance, as well as cheapness and reproducibility will help in the diagnosis of trauma lesions and prompt and timely treatment. And CT scans should be used only in limited cases and special indications.

CONCLUSIONS

The results show E-FAST is a suitable alternative to CT scan in the diagnosis of hemothorax, pneumothorax, and free fluid in the abdomen, vulva, and pericardial cavity. The reason for decreased sensitivity and specificity of E-FAST in the diagnosis of abdominal bleeding in this study was mostly due to several cases of retroperitoneal bleeding that could not be detected by FAST but were observed by CT scan. Due to portability, safe body, no need for contrast, fast performance, as well as cheapness, and reproducibility, it will be a great help in diagnosing trauma-related lesions and prompt and timely treatment. CT scan should be used only in limited cases and special indications.

Evaluation of the expression level of Sine oculis homeobox homolog 1 in cervical cancer tissue in comparison with healthy adjacent tissue

Ehsan Kakavandi[1], Ebrahim Faghihloo[2], Mahdieh Farzanehpour[3,4], Mohammad Farahmand[1], Mehdi Yaseri[4], Talat Mokhtari-Azad[1]

Abstract: *Background and Aim: This study aimed to investigate the expression level of Sine oculis homeobox homolog 1(SIX1) in normal and cancerous cervical tissues. Methods: Real-time PCR was used to evaluate SIX1 expression level in fresh surgically obtained cervical biopsies. Also, cervical specimens were tested for HPV DNA detection by MY09/11, GP5+/6+ nested PCR method. Results: The expression level of SIX1 mRNA in Cervical cancer was markedly higher than in normal cervical tissue (p<0.0001). Moreover, HPV DNA was detected in 100% of cases and 21.05% of controls (P<0.0001). Conclusions: This finding indicates that increased SIX1 expression might be of relevance to the pathogenesis of cervical cancer. Perhaps, studies to find agents that specifically target SIX1, develop novel anti-cancer and anti-metastasis drugs. This idea has to be investigated in future clinical studies.*

Keywords: *cervical cancer, SIX1, molecular mechanism, pathogenesis, expression level*

INTRODUCTION

Cervical cancer (CC) is the fourth most common cancer in women with worldwide estimated 527,000 cases and 266,000 deaths in 2012 [1, 2]. Persistent infection with high-risk Human papillomaviruses (HPVs) known as the fundamental cause of CC; although, most of the infected women usually recover spontaneously and only a small proportion progress to CC [2, 3]. HPV E6 and E7 oncoproteins not only inactivate the tumor suppressors p53 and Rb respectively but also modulate a plethora of cellular proteins and signalling pathways related to DNA replication, cell survival, apoptosis, anoikis, epithelial to mesenchymal transition (EMT), anchorage-independent growth (AIG) and angiogenesis. Accordingly, alteration of these cellular cascades leads to cell immortalization, transformation and finally occurrence/development of CC and metastasis [4, 5]. Among these cellular factors, Sine oculis homeobox homolog 1 (SIX1) play a crucial role in CC onset and metastasis [6]. SIX1 is one of the important members of SIX family. This family, including a series of transcription factors, are homolog of the Drosophila sine oculis (so) gene and have a total of six members (SIX1 to SIX6) in vertebrates. Among them, SIX1 has attracted the attention of many researchers recently. SIX1 gene is located on human chromosome 14q23 and its structure composed of two conserved domains, the homeodomain (HD) and the SIX domains (SD). Many studies have shown that SIX1 is essential for the development of

various human organs in physiological conditions and overexpressed in multiple human cancers, also associated with metastatic phenotype [7, 8]. It is indicated that SIX1 stimulates DNA replication, cell proliferation and maintains survival conditions in CC cells. In the other hand, HPV E7 oncoprotein can induce SIX1 overexpression. Consequently, HPV can obtain opportunity of effectively persistent infection in cervical cells and develop CC [9, 10]. Advanced stages of CC have not effective treatments and most of patients with metastatic CC die. Thus, the better understanding of HPV-induced CC molecular mechanism is indispensable and can assist to introduce more effective novel therapeutic approaches for HPV-induced CC prevention and treatment. In the present study, we evaluate the expression level of SIX1 mRNA by real-time PCR in CC biopsies in comparison with healthy adjacent tissues.

MATERIAL AND METHOD

2.1. Specimens

A total of 38 histopathologically confirmed fresh cervical biopsies consist of 19 cancer samples and 19 normal samples were surgically collected from the Department of gynecology at Imam Khomeini hospital in Tehran, Iran. Normal subjects were women referring to gynecology department of hospital for any cause (for example ovarian cancer), except for cervical involvement. No subjects received preoperative radiotherapy, chemotherapy, or other treatment. The study was approved by the medical ethics committee from Tehran University of Medical Sciences and written informed consent was obtained from all patients before enrollment (approval number 1395.1301).

2.2. DNA Extraction

DNA was extracted from biopsies by the High Pure Viral Nucleic Acid Kit (Roche, Mannheim, Germany) according to manufacturer's instructions. A Nanodrop spectrophotometer (Nanodrop Technologies) was used to determine DNA concentration and purity.

2.3. PCR Analysis

First, we confirmed the integrity of extracted DNA by amplification of a housekeeping gene β-globin (act as an internal control) using PCO3/PCO4 primers. The reaction conditions were as follows: 40 cycles of 95 °C for 1 min, 55 °C for 1 min, and 72 °C for 2 min and a final extension at 72 °C for 7 min. Then, the presence of HPV DNA was examined by nested PCR assay in all of the positive specimens for the β-globin gene. For this purpose, we used MY09/11 outer followed by GP5+/6+ inner primers (are located within the L1 region of the HPV genome. The Sequences (5 to 3) of all PCR primers are listed in table 1. The temperature cycling program in the first round (MY09/11) and second round (GP5+/6+) PCR was identical as follows: 94°C for 4 min, 40 cycles of 94°C for 1 min, 42°C for 1 min, 72°C for 30 s and a final extension at 72 °C for 4 min [11].

2.4. RNA Extraction

The total RNA from tissue specimens was extracted using Trizol reagent (Invitrogen, Carlsbad, CA, USA) according to the manufacturer's protocol. The extracted RNA was eluted in 50 µl Diethylpyrocarbonate (DEPC) water. The concentration and purity of RNA were determined by Nanodrop spectrophotometer (Nanodrop Technologies). In order to the prevention of genomic DNA contamination, RNA samples were treated with RNase-free DNase I (Invitrogen, Carlsbad, CA, USA) according to the manufacturer's instructions.

2.5. Real-Time PCR

One microgram of RNA samples was reverse transcribed to cDNA using RevertAid First Strand cDNA Synthesis Kit (Thermo Scientific, USA) following the kit's instructions. Real-time PCR reactions were carried out in duplicate with Applied Biosystems 7500 Real-Time PCR system using SYBRs Premix ExTapTM II (Takara, Japan) and specific primers that listed in Table 1 [12]. Glyceraldehyde 3-phosphate dehydrogenase (GAPDH) was applied as an internal amplification control. The 2−ΔΔCT method was used for relative quantification of SIX1 expression levels and results were normalized to GAPDH, as a housekeeping gene.

2.6. Statistical analysis

Statistical analysis was performed using the SPSS 18.0 (SPSS Inc., Chicago, IL, USA). Variables were compared between groups using the Fisher's exact test or student's t-test as appropriate. Numerical results are expressed as the mean ± SEM. The p-values of <0.05 were considered statistically significant.

RESULTS

3.1. Demographic characteristics

The mean age of the women in the CC group and control group was 61.3 ± 10.2 and 36.0 ± 8.3 years, respectively. Based on statistical analysis, the mean age in the CC subjects was significantly higher than the control group (p-value <0.0001).

Table 1: Sequences of primers used for real-time PCR reactions in current study

Primers	Sequence (5′–3′)
β-globin	PCO3 (Forward) ACACAACTGTGTTCACTAGC PCO4 (Reverse) CAACTTCATCCACGTTCACC
HPV	MY09 (Forward) CGTCC(A/C)A(A/G)(A/G)GGA(A/T)ACTGATC MY11 (Reverse) GC(A/C)CAGGG(A/T)CTATAA(C/T)AATGG GP5+ (Forward) TTTGTTACTGTGGTAGATACTAC GP6+ (Reverse) AAAAATAAACTGTAAATCATATTC

HPV, Human papilloma virus; GAPDH, Glyceraldehyde 3-phosphate dehydrogenase; SIX1, Sine oculis homeobox homolog 1

3.2. Prevalence and type of HPV infection

HPV DNA was detected in 100% (19/19) of the cancer cases and 21.1% (4/19) of normal cervical specimens (Table 2). There was a significant difference between the two studied groups (p<0.0001). After sequencing analysis of HPV-positive specimens, we identified HPV-16 in all of the CC samples. Also genotyping of 4 HPV-positive specimens in normal group was HPV-16: 2 cases, HPV-66 and HPV-68: each one was one case (Table 2).

Table 2: Demographic and clinico-pathological characteristics in patients with cervical cancer and without cervical cancer

Variables	Cases (n = 19)	Controls (n = 19)	p-value
Age (mean years)	61.3 ± 10.2	36.0 ± 8.3	<0.0001, t-test
HPV positivity	19 (100%)	4 (21.1%)	<0.0001, Fisher'sisher's exact test
HPV type	HPV-16 = 19	HPV-16 = 2, HPV-66 = 1, HPV-68 = 1	

HPV, Human papilloma virus

3.3. SIX1 mRNA expression

Relative real-time PCR results showed that the mean SIX1 mRNA expression in the CC patients was 2.61 ± 0.09 and in the normal subjects was 1.12 ± 0.03 (Table 3).

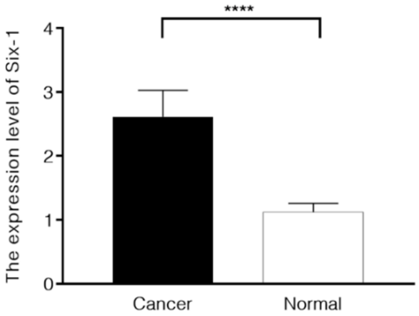
Table 3: Expression level of SIX1 in patients with cervical cancer and without cervical cancer

Gene		Cases	Controls
*SIX*1	Mean ± SE	2.61 ± 0.09	1.12 ± 0.03
	CI	2.42 - 2.79	1.06 - 1.18
	Minimum expression	1.94	0.92
	Maximum expression	3.47	1.39
	p-value	<0.0001 t-test	

SIX1, Sine oculis homeobox homolog 1; SE, standard error; CI, confidence interval

Then, statistical analysis revealed that SIX1 mRNA levels were significantly (p<0.0001) higher in CC tissue compared to the normal cervical tissue (Figure 1).

Figure 1: The expression level of SIX1 in CC and normal cervical group. Data are presented as mean ± SEM and the fold increase of transcripts for SIX1 mRNA normalized by GAPDH housekeeping gene. ****p<0.0001.



DISCUSSION

The sine oculis homeodomain (SIX) proteins are a family of evolutionarily conserved transcription factors that play a pivotal role in both embryogenesis and carcinogenesis. The homeoprotein transcription factor SIX1 is one of the members of this family that has attracted much attention from the scientific community in recent years [13]. Based on the previous studies, SIX1 upregulated in several human cancers such as breast, ovarian, cervical, liver, rhabdomyosarcoma and Wilms' tumor, also contribute to initiation and metastatic development of these malignancies. Researches have also observed the SIX1 overexpression strongly correlated with poor prognosis and shortened overall survival in cancer patients [14-16]. Consistent with previous studies, we demonstrated the SIX1 mRNA levels is significantly higher in CC than normal cervical tissues. The results of previous studies showed that SIX1 can drive cancer stem cell phenotype and EMT, also lymphangiogenesis, consequently metastasis via stimulation of the TGF-β signaling pathway and VEGF-C, respectively [17-19]. EYA2 act as a coactivator for SIX1, thus mediate its transcriptional activation. Previously it has been shown that inhibition of SIX1-EYA2 complex formation, may be a promising and more effective approach for treatment of cancer and tumor metastasis [20]. In CC cells, SIX1 act as principal regulator of DNA replication, as well as a key factor in metastasis process. Therefore, SIX1 upregulation can lead to malignant proliferation of cervical cells, also metastasis through stimulation of DNA replication-related genes and a5b1 integrin, respectively [10, 21]. Interestingly, high-risk HPV employ various mechanisms to promote metastasis in CC [4]. Anoikis, meaning homelessness, is a detachment-induced cell death. Anoikis resistance, EMT, AIG, and angiogenesis are important cellular events that closely associate with cancer metastasis [22]. Hr-HPV E7 oncoprotein can stimulate SIX1 overexpression in CC. SIX1 consider as an EMT-activating factor, thus its upregulation result in EMT through increasing of ZEB1 and decreasing of E-cadherin. Indeed, SIX1-induced EMT, increase cell survival in detached cancerous cells and drive anoikis overcoming and finally, metastatic dissemination [9]. In the present study, among the total of 38 fresh surgically obtained cervical biopsies, 100% (19/19) and 21.1% (4/19) were positive for HPV DNA, in CC and normal adjacent groups, respectively. Then, sequencing analysis revealed all of HPV-positive specimens in CC group were HPV type 16 that highlighted the indispensable role of HPV-16 in CC onset and progression. The previous studies demonstrated the high risk HPV-16 and HPV-18 account for about 70% of CCs [23]. In current study, four HPV-positive specimens in normal cervical group were: two samples of HPV-16 and one sample of HPV-66 and HPV-68. Based on international agency for research on cancer (IARC) classification, HPV-66 belongs to 2B category (probably carcinogenic). Also, HPV-68 belongs to 2A category (possibly carcinogenic) [24]. Our outcomes corroborated previous reports specifying that the SIX1 involved in the tumorigenesis of cervical cancer [13, 25]. The main limitation of our work was low sample size. In conclusion, SIX1 upregulated significantly in CC, which in turn induces TGF-β, VEGF-C and ZEB1 that collectively can have an association in the tumorigenesis and metastasis of CC.

CONCLUSIONS

We demonstrated SIX1 expression levels was frequently expressed in CC tissues. Also, HPV DNA was detected in 100% (19/19) of the cancer cases and 21.1% (4/19) of normal cervical specimens. HPV can upregulate SIX1 in CC. In addition, SIX1 can contribute to the development of CC and lymph node metastasis of cervical tumors. Nevertheless, the precise biologic role of SIX1 in CC is unclear yet and future works should study on the larger number of patients.

Evaluation of the protective effect of coenzyme Q10 on the growth process of embryos from in vitro fertilization in laboratory mice treated with cyclophosphamide

Soheil Vazifedust[1], Hadi E.G. Ghaleh[1], Farshad N. Asiabani[1]

Abstract: *Cyclophosphamide is an anticancer drug that acts as an alkylating agent after metabolism in the liver. Despite its many clinical applications in cancer treatment, this drug has toxic effects on the body's organs, especially the genitals. One of the most critical side effects is a change in the function of the female reproductive system, which can lead to infertility. This study aimed to investigate the antioxidant effects of coenzyme Q10 on cyclophosphamide-induced toxicity in vitro fertilized embryos in mice. In this experimental study, 24 female mice weighing 25 g 4 groups of 6 were divided and treated for 21 days. The first group (control group), solvent (cyclophosphamide) including DMSO and PBS (0.1 ml intraperitoneally), the second group (sham group), cyclophosphamide at a dose of 10 mg/kg was injected as a single dose, and the third group (experimental group), along with single-dose cyclophosphamide, coenzyme Q10 at a dose of 200 mg/kg/day was injected intraperitoneally and the fourth group (positive control group), only coenzyme Q10 at a dose of 200 mg/kg/day was injected intraperitoneally. At the end of the treatment period, ovulation stimulation was performed using PMSG and HCG hormones. Six adult male mice were used to prepare normal sperm. The animals were facilitated after anesthesia. After extraction of regular eggs and sperm and fertilization in HTF + 4 mg BSA medium, the fertilized eggs were incubated for 120 hours, and the embryonic developmental stages were examined during this period. Were analyzed by ANOVA and comparison of ratios. Cyclophosphamide significantly reduced oocyte quality, fertilization rate, pre-implantation embryonic development, and embryo quality. Coenzyme Q10 (Co Q10) significantly reduced the adverse effects of cyclophosphamide.*

The present study showed that crocin could protect the fertility of the female sex against damage caused by cyclophosphamide.

Keywords: *cyclophosphamide, ovary, coenzyme Q10, mice, fertility*

INTRODUCTION

Operation of inguinal hernia is one of the most common procedures in the general surgery field. The prevalence of inguinal hernia is between 15-45% at different ages [1-3]. There are two categories of inguinal hernia, direct and indirect, that included 24 to 50% of all types of hernia, respectively [4-7].

Some studies reported chronic obstructive pulmonary disease, chronic cough, benign prostatic hyperplasia, chronic constipation, family history of hernia, previous right lower quadrant incision, smoking, collagen diseases, physical activity, and bearing the burden can trigger inguinal hernias [5-10].

The inguinal hernias can develop discomfort, pain, and dysfunction in the patient, and also it can cause a cosmetic problems for most patients [2-4]. Severe complications of this disorder, which often occur following hernia entrapment and suppression, require emergency intervention. These include obstruction, ischemia, and gangrene of the bowel or any organ trapped inside the hernia sac [4-7].

A surgical procedure is the standard treatment for this disease. Today, there are several techniques of surgery for it, and surgeons associated with circumstances chose a surgery strategy. The main purpose of surgery is to treat patients and decrease the recurrence chance of the disorder [11-15].

Inguinal hernia repair surgery has several potential complications such as hernia recurrence, pain, osteitis of the pubis, Damage to the cord and testicles, hematoma, and testicular swelling [1-3, 5]. There are two main approaches to operation including open surgery and laparoscopy. Also, there are several techniques to repair the herniation site such as classical and preperitoneal techniques. The classical method is a simpler procedure than other methods of repair conducted by most surgeons. Various conventional methods like Bassini's applying suture material are in usage despite the laparoscopic hernia repair [16-18]. Suture repair is related to a significant tension on the suture line. This is possible to induce ischemia of the tissues and final failure of repair causing recurrence [18-20].

Open surgical techniques include two categories of tissue repair and mesh repair methods. More traditional methods are based on initial tissue repair, but today with the production and presentation of industrial meshes, non-traction hernia repair with mesh is the standard method of inguinal hernias surgery [9-6]. Lichtenstein et al. reported the concept of tension-free hernia repair through a synthetic proline mesh that ensures promising outcomes of hernia repair in the long term [1-3].

Preperitoneal repair is one of the pre-peritoneal methods, the mesh is placed under the transversal fascia and right on the peritoneum, especially in cases of recurrent hernias after tissue repair methods. In this method, the peritoneal space is released through the anterior access, a 15 by 15 cm mesh is implanted on the peritoneum and fixed to the umbilicus and symphysis of pubis with non-absorbable thread, and then tissue repair with nylon loop thread is done [13-14].

This study aimed to compare the complications of Surgical Repair in inguinal hernia with Bassini, Lichtenstein, and Preperitoneal met Exposure to exogenous materials, whether natural or man-made, has a profound effect on vital processes and reduces or destroys reproductive capacity [1]. In the female animal, if it comes in contact with chemicals, it affects the oocyte cell, which is in various stages of primary, primary, secondary, or ovulation. Most chemotherapeutic agents are mutagenic and cause defects in sex cell chromosomes. Alkylating agents such as cyclophosphamide are among the significant chemotherapeutic agents used to treat cancers and autoimmune diseases [2]. This compound is a cytostatic drug from the oxazaphosphorine group and alkylated nitrogen mustard derivatives [3].

Cyclophosphamide is converted by its oxidase enzymes in the liver to its active metabolite, 4-hydroxy cyclophosphamide, which interacts with its totomer called aldophosphamide. Most aldophosphamide is oxidized by the enzyme aldehyde dehydrogenase (ALDH) to carboxy-phosphamide, and only a small amount of aldophosphamide is converted to mustard phosphor amid acrolein [4]. Despite its wide range of clinical applications, this drug causes reproductive toxicity. Studies have shown that cyclophosphamide disrupts the process of spermatogenesis by increasing sperm DNA damage [5]. Ovarian dysfunction decreased sex hormones, and reduced follicle count have also been reported with cyclophosphamide [6]. Cyclophosphamide also destroys primary follicles and, due to reduced follicular reserve, harms the reproductive system, and causes infertility and premature menopause in females [7]. Cyclophosphamide products chromatin and some of its effects have been observed in the next generation of F2 [8]. Injection of cyclophosphamide into pregnant mice on the thirteenth day of the fetus can cause a defect in the synaptic process as partial synapses or no bilateral synapses on the eighteenth day of the fetus [9].

Oxidative stress results from an imbalance between the production of oxygen free radicals versus the antioxidant defense capacity of the cell, leading to the production of free radicals, including superoxide anion (O_2), hydroxyl radicals (OH), and non-radical derivatives of oxygen such as hydrogen. Peroxide (H_2O_2). These free radicals are highly unstable and react rapidly and non-specifically with biomolecules, leading to the development and spread of cellular damage including plasma membrane peroxidation, amino acid, nucleic acid oxidation, apoptosis, and necrosis. Finally, it leads to a decrease in the viability and development of embryos in the culture medium [10,11]. Reproductive disorders in both males and females caused by oxidative stress have been reported. The effect of reactive oxygen species (ROS) levels on zygotes or early embryonic development has been identified. Oxidative stress may be responsible for fetal toxicity in the hydrosalpinx [12]. The addition of antioxidants such as vitamins C and E to the culture medium improves the blastocyst development ratio in mouse embryos [13]. It enhances the fertility ratio and increases implantation [11]. Cyclophosphamide, as an important and effective drug in the treatment of cancer, despite its improvement in cancer patients, acts as an oxidative stress-producing agent in the body and increases the production of ROS. Therefore, to modulate and prevent the effects of oxidative stress caused by cyclophosphamide, coenzyme Q10, which has an antioxidant role, can be helpful. Coenzyme Q10 (CoQ10), a fat-soluble molecule in almost all cell membranes, is located inside the mitochondrial membrane. CoQ10 is an essential component for transporting electrons in the mitochondrial respiratory chain to produce cellular energy. In addition, the reduced form of CoQ10, known as ubiquinol, acts as an antioxidant in cellular metabolism by inhibiting lipid peroxidation, protein, and DNA oxidation [14,15]. The amount of CoQ10 in tissues is often reduced in many system-related pathological conditions such as diabetes and Alzheimer's and prion diseases, as well as the use of chemicals. Although CoQ10 is synthesized in almost all normal tissues, CoQ10 tissue levels gradually decrease with age [16]. Defects in CoQ10 synthesis with specific clinical disorders associated with high-energy consuming tissues, including skeletal muscle, endocrine glands, and nervous system [17]. Studies have shown that CoQ10 supplementation causes a significant increase in CoQ10 levels in some tissues such as muscle, sperm, and plasma, and a substantial increase in the adrenal glands and ovaries [18,19]. Therefore, CoQ10 supplementation protects cells against ROS-induced damage due to its antioxidant properties, strengthening endogenous cell antioxidant systems.

Since no study has been performed on the effect of coenzyme Q10 as an antioxidant in reducing the effects of oxidative stress induced by cyclophosphamide on the growth of in vitro fertilization embryos, in this study, the protective effect of coenzyme Q10 on Improving the growth process of in vitro fertilization embryos was studied in cyclophosphamide-treated mice.

METHOD

In this experimental study, 24 female rats weighing approximately 20-25 g were randomly divided into four equal groups of 6 and treated for 21 days. Animals under standard conditions with a temperature of 22.2° C, humidity 30-60%, and the light cycle, 14 hours of light and 10 hours of darkness were maintained. Water and food were freely available.

The control group (cyclophosphamide) including DMSO and PBS (0.1 ml intraperitoneally), the sham group with a dose of 10 mg/kg was injected as a single dose of only cyclophosphamide, experimental group 1, with a single dose of cyclophosphamide, coenzyme Q10 at a dose of 200 mg/ kg/day was The control group (cyclophosphamide) including DMSO and PBS (0.1 ml intraperitoneally), the sham group with a dose of 10 mg/kg was injected as a single dose of only cyclophosphamide, experimental group 1, with a single dose of cyclophosphamide, coenzyme Q10 at a dose of 200 mg/kg/day was injected intraperitoneally into the positive control group, only coenzyme Q10 at a dose of 200 mg/kg/ day was injected intraperitoneally. Ovulation induction was required for this study. For this purpose, after the end of the treatment period and 72 hours before in vitro fertilization (IVF), 5.7 units of HCG (made by Folligon, Netherlands) in a volume of 0.1 ml was injected a volume of 0.1 ml and 48 ml. An hour later, 5.7 units of HCG (made by Folligon, Netherlands) in a volume of 0.1 ml was injected intraperitoneally. Ovulation was performed 13 hours after HCG injection.

The first step in IVF was to prepare normal sperm from 6 adult male laboratory mice by injecting ketamine (25 mg/kg body weight, intraperitoneally) under anesthesia with a high dose of easy ketamine. The skin of the abdomen was then sterilized with 70% ethanol. After making an incision in the abdomen and separating the connective tissues, we saw around the tail of the epididymis with some vas deferens from the testicle and into a 3 cm dish containing a medium. HTF culture, containing 4 mg/kg BSA (Sigma, USA), was previously transferred to the incubator for exchange. After making several incisions in the tail of the epididymis and pressure in the vas deferens to expel sperm, Petri the dishes were placed inside a carbon dioxide incubator. After 30 minutes, the sperm were released and spread in the environment. The sperms were then washed and separated using a flotation method. In this study, standard sperm samples with motility above 80% and one million per ml of culture medium were used. The second stage of work was ovulation in female mice. For this purpose, 13 hours after HCG injection (following day), animals after anesthesia with ketamine injection (25 mg/kg body weight, intraperitoneal) and injection. The high dose of ketamine was facilitated, then the fallopian tubes were removed and placed in HTF + 4mg/ml BSA culture medium at 37° C, which was prepared in advance, and the eggs were removed using an autopsy method. After washing, they were transferred to the fertilization medium under mineral oil containing HTF culture medium (containing 4 mg/ml BSA). Then the sperms were transferred to the culture medium in the amount of one million per ml of culture medium. It took about 3 to 5 hours after the sperm were added and thus, the zygotes were obtained. Zygotes from all groups were cultured in HTF medium for 120 h and embryonic developmental stages were evaluated under the inverted microscope to evaluate the effect of oxidative stress due to cyclophosphamide administration and the protective effect of coenzyme Q10. Fission rate was assessed 24 hours after culture and in zygotes in each group, embryos in terms of fragmentation, embryonic development, and the number of embryos stopped due to various factors such as embryonic slippage, necrotic, fragmentation, and the presence of cytoplasmic vesicles occurred. Embryo quality, number of embryos grown, and incision percentage were evaluated by examining the percentage of two-cell embryos, the number of stopped embryos, and the rate of blastocysts formed during 120 hours of incubation in each group.

RESULTS

The control group differentiated the percentage of embryos from blastocysts with appropriate quality after 120 hours of incubation, and the percentage of embryos that stopped at different stages of development. B, cyclophosphamide group, a small percentage of embryos have reached the blastocyst stage and the resulting blastocysts are not of good morphological quality. C, a cyclophosphamide-treated group with coenzyme Q10 (experimental) compared with the cyclophosphamide control group, a high percentage of embryos reached the blastocyst stage and the resulting blastocysts are of good morphological quality, and a small percentage of embryos are stopped. D, coenzyme Q10% higher percentage of embryos reach blastocyst and percentage of embryos are stopped at different stages (invert microscope, magnification × 400) (Figure 1).

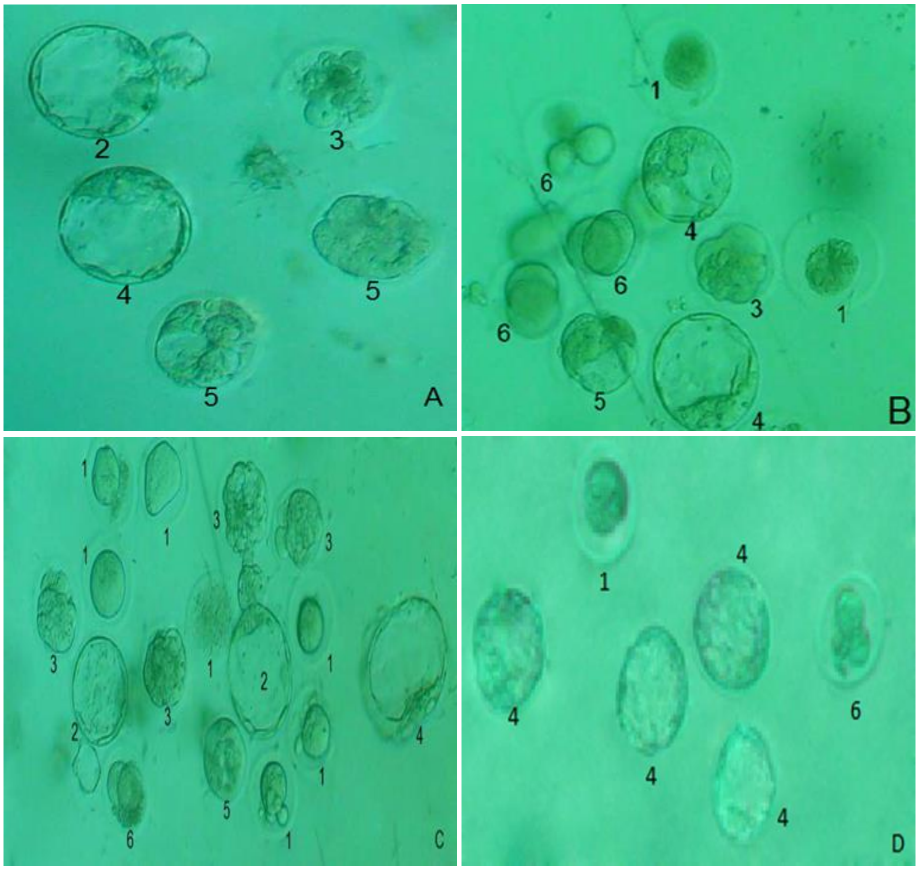

Figure 1: Fetal growth photomicrograph: A: Control group, B: Cyclophosphamide group, C: Cyclophosphamide with coenzyme Q10, D: Coenzyme Q10

1. Oocyst; 2. The fetus is being hatched; 3. Merola; 4. Blastocyst; 5. Primary blastocyst; 6. Fetal fetus

The interaction of different drug groups and antioxidants on the measured parameters showed that the effect of drug treatment on the number of oocytes was significant (P <0.05), so the highest number of oocytes was obtained from the control group and the lowest amount belongs to the cyclophosphamide group only. It was also shown that the mean number of oocytes in the cyclophosphamide group with coenzyme Q10 was almost similar to the control group, and there was no significant difference with this group (Figure 2).

The effect of antioxidant treatment in the cyclophosphamide group with coenzyme Q10 on the mean number of zygotes was significant compared to the cyclophosphamide group (P <0.05), but this increase was not significantly different from the control group among the treated groups. The highest number of zygotes belonged to the group that received coenzyme Q10 alone and was not substantially different from the control group; the lowest number of zygotes was obtained from the group that received only cyclophosphamide (Figure 3).

The mean of two-cell zygotes in cyclophosphamide-receiving groups with coenzyme Q10 was not significantly different from that of cyclophosphamide despite increasing the number of two-celled zygotes (Figure 4).

Figure 2

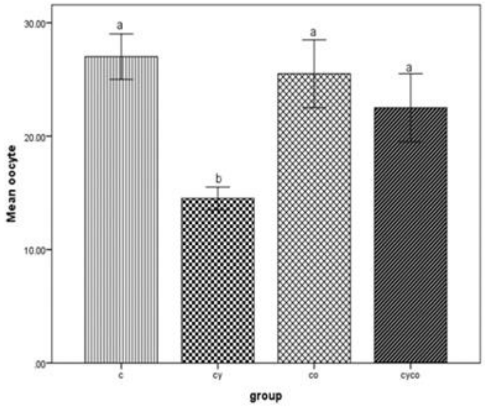

Figure 3

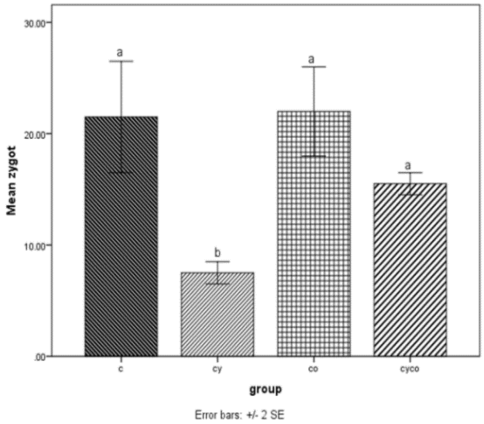

Figure 4

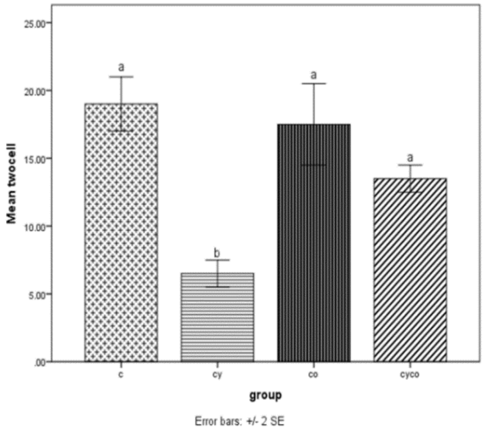

The effect of antioxidant treatments on the number of blastocysts was. The highest amount belonged to the control group and the lowest amount belonged to the group that received only cyclophosphamide (Figure 5).

The mean number of blastocytes in all groups receiving cyclophosphamide along with coenzyme Q10 was significantly different from the cyclophosphamide group (P <0.05). Regarding this parameter, the group receiving coenzyme Q10 alone did not have a significant difference from the control group (Figure 6).

Figure 5

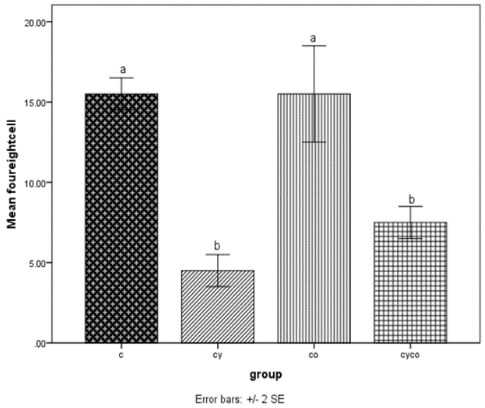

Figure 6

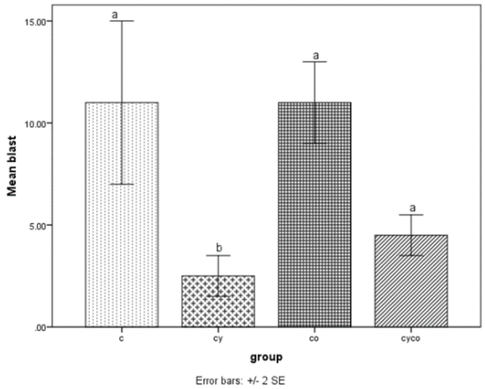
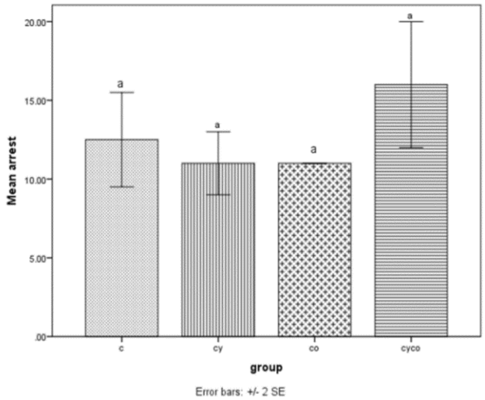


The highest number of discontinued embryos was observed in the cyclophosphamide group and the use of coenzyme Q10 with cyclophosphamide significantly reduced the mean number of discontinued embryos (P <0.05) (Figure 7).

Figure 7



DISCUSSION

Cyclophosphamide causes reproductive toxicity by inducing oxidative stress, which is reduced by the concomitant administration of antioxidants. The ability of cyclophosphamide to produce free radicals, lipid peroxidation, and oxidative stress has been reported in laboratory mice [20].

Previous studies have shown that low doses and long-term use of cyclophosphamide in male and female mice impair fertility [21,22]. It changes the development of the next generation [23]. Intracellular thiol levels appear to play an essential role in determining cell susceptibility to cyclophosphamide-induced damage [24].

4-Hydroxycyclophosphamide can react with cellular thiols to produce a thio-alkyl derivative. Derivatives produced in equilibrium with 4-hydroxycyclophosphamide are considered alkylating agents [25] and can induce oxidative stress. Cyclophosphamide has also been shown to have immunosuppressive properties, which are related to its induction of oxidative stress [26].

Due to the effect of cyclophosphamide on chromatin of sex cells and DNA failure in the nucleus of oocyte cells, some of its effects appear in the next generation [8]. One study found that in cyclophosphamide-affected larvae, after extraction in a culture medium, the meiotic division was inhibited 48 hours later, whereas, in animals, fertility may continue in humans. As a result, under the influence of chemotherapy agents, the development of embryos is disrupted and anomalies develop in them [27]. This study was performed to modulate the side effects of oxidative stress exerted by cyclophosphamide on the growth process of in vitro fertilization embryos using coenzyme Q10 as an antioxidant. In this study, the growth rate and quality of embryos obtained from in vitro fertilization in the control group showed a significant decrease compared to the control group.

These observations indicate the toxic effect of cyclophosphamide on reproductive activity through oxidative stress, which is co-administered. Coenzyme Q10 (Co Q10), as an antioxidant, attenuated this toxic effect of the drug and increased the quality of fetal growth in the laboratory. Injection of high-dose cyclophosphamide into female mice mainly affects the primary follicles and disrupts other ovarian characteristics such as ovulation, egg transfer, and end endocrine regulation [28].

In a study conducted on the effect of Khuzestani Marzeh essential oil on in vitro fertilization of adult female mice treated with cyclophosphamide, administration of safflower extract with cyclophosphamide improved the growth of embryos obtained from in vitro fertilization.

Other studies on the modification or prevention of side effects of chemotherapy drugs by antioxidant agents have shown the toxic effects of cyclophosphamide on sperm morphology and ovarian tissue, are protected by lycopene and alginic acid as antioxidants [29].

The protective role of vitamin E against oxidative stress induced by cyclophosphamide has been demonstrated in mice. This action of vitamin E may be the result of the destruction of free radicals as well as the stimulation of the release of anterior pituitary gonadotropins [30]. Also, the presence of antioxidants in culture media improves the blastocyst development ratio in mouse embryos and improves the fertility ratio, and increases implantation [31].

CONCLUSION

Considering all the results obtained along with their interpretation, the present study reinforces the idea that the reproductive toxicity caused by cyclophosphamide administration occurs due to oxidative stress, and that a potent antioxidant such as coenzyme Q10 can regenerate the reproductive system. Protects against oxidative stress damage caused by cyclophosphamide, which often causes infertility. In the present study, coenzyme Q10 was able to increase the quality of germ cells, and fertilization rate, improve fetal growth in the laboratory, and reducing cessation at different stages of embryonic development. effective.

REVIEW ARTICLE

Evidence based medicine: lessons learned from the NATO Military Medical Center of Excellence

Tomáš Vašek[1], Jaroslav Žďára[1], Petr Král[2], Milan Růžička[1], Michal Potáč[1], Petr Smola[1], John Quinn[3]

Abstract: *Evidenced-based medicine drives best practices. The Lessons Learned (LL) process in clinical medicine for deployed and military support services drive the NATO Military Medical Center of Excellence (MILMED COE). This review article focuses on the Lessons Learned process and its use in NATO and partner countries medical services. Organizational learning drives development and progress; capturing lessons from mistakes, colleagues' interactions and institutional experience can be lost without an organized lesson learned process. Therefore, in 2014, NATO institutions and Centers of Excellence across disciplines began to focus on the quality management, information sharing and evidence-based practices to maximize outcomes. Since this inception, NATO has implemented the Lessons Learned process and expanded the impact across the alliance in order to save life and prevent illness. The Lessons Learned process and sharing of experience is also a way to improve the quality of care in the military medicine, from preventive, epidemiological, trauma related, casualty evacuation and forward surgical care, among many others, to the medical standardization and organization of military medical services. The Lessons Learned process is an undertaking and an instrument that can also be used to achieve better international and civil-military cooperation. Finally, we deal with the current situation and use of the information obtained from the areas of military health care.*

Keywords: *evidenced-based medicine, knowledge management, lessons learned, Military Medical Service, NATO*

INTRODUCTION – APPLICATION OF THEORY OF LEARNING

Each scientific discipline must be driven by data. One of the areas from which information can be drawn is Lessons Learned, through analysis and a constant cycle of learning and sharing data. This is most applicable in the military medicine and across the healthcare sector, where shared information can be used from various areas, rooted in preventive medicine, epidemiology, traumatology, and others adding to military medicine and healthcare organization and administration.

Institutions that promote health act as microcosms of organism that can evolve through adaptation. As Charles Darwin posited, it's not the strongest survivor, not even the most intelligent, but the one who can best adapt. Every living organism adapts best by learning from past mistakes. In a broader sense, it is about adapting to the environment, as well as the active role of the individual and the choice based on challenges. But learning is not mere adaptation, but it is an active process in which an individual acquires (changes, adapts, and repeats) something that is new. Learning outcomes are actively created personal hypotheses and meanings of reality [1].

There are many theories of learning, but the process we describe in this paper focuses on the theory of Classical Conditioning (I.P. Pavlov), Thorndike's theory of Instrumental Conditioning, Skinner's theory of Programmed Learning, and the theory of Learning through Imitation. Simply put, we

[1] Faculty of Military Health Sciences, University of Defence, Czech Republic
[2] NATO Centre of Excellence for Military Medicine
[3] Prague Center for Global Health, Institute of Hygiene and Epidemiology, First Faculty of Medicine, Charles University

will do, repeat and develop what we have done and have some positive effect in a particular area. Conversely, we discuss what happened and had some negative consequences that should not be repeated. Based on applying these hypothesis listed above and core knowledge, every organization that wants to survive must behave to the basic strategy of learning from past mistakes.

THE WAY OF THE LESSONS LEARNED PROCESS TO MEDICAL SERVICES OF THE NATO ARMIES

In the early years of the 21st century, NATO understood the importance of transformation and has become a learning organization that has the ability to be constantly flexible and adaptive to remain the central core of European and North Atlantic Security structures in the promotion of safety and security across international communities. For this reason, NATO has issued guidelines outlining the process of learning and sharing experiences, with the clear aim of providing a standardized structure and process that enables this ability in all alliance command structures [2].

Moreover, as outlined within the Armed Forces Declaration, signed by the NATO Heads of State during the NATO Summit, Wales 2014, NATO was directed to enhance the sharing of best practices and lessons learned in support of its Armed Forces personnel and their families [3]. Through the Military Committee (MC), the Committee of the Chiefs of Military Medical Services in NATO (COMEDS) requested that the NATO Centre of Excellence for Military Medicine (MILMED COE) prepare a way ahead to be presented at the 42nd COMEDS Plenary. The proposal was approved and subsequently endorsed by the International Military Staff (IMS) and Military Committee (MC) [4].

LESSONS LEARNED PROCESS AS A PART OF KNOWLEDGE MANAGEMENT

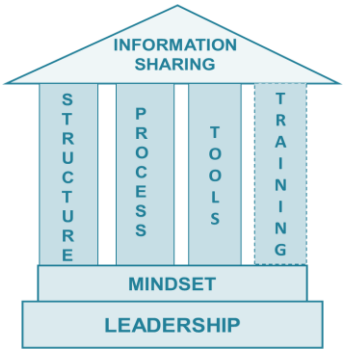
Lessons Learned is defined as a major component of Knowledge Management (KM), not only in the military, but also in government and commercial organizations [5]. The priority objective of Knowledge Management is to achieve higher performance of the organization in fulfilling its tasks in a dynamic, asymmetric and unstable environment (i.e. across the domains of land, sea, air, space and cyber). Therefore, gaining knowledge and experience is a process whereby the Lessons Learned are explored in order to find the best way to deal with the situation and share the outcome to all stakeholders who can benefit from it, and preferably mitigate and reduce mortality and morbidity.

In addition, it is a process allows an organization to learn from its mistakes or use its achievements. Thus, Lessons Learned is an instrument for the continuous process of improving each organization based on evidence [6]. The essence of this process is that it reduces the risk of error repetition in the organization, and the likelihood of repetition of success increases. The introduction of this process within the military health service is important not only for updating the core doctrine that drives best practices, but also for the comprehensive preparation of units in both peacetime and deployed operations.

According to the NATO Bi-Strategic Command Directive 080-006 [7], which is a strategic document of the Lessons Learned process, the following components – the pillars through which the process is implemented – are needed (Figure 1):

- Processes – links between elements to implement the process, standardize the process to ensure its compatibility and universality both in the NATO structure and in collaboration with other partners.
- Structure – elements (bodies) that are responsible for individual subprocesses and which guarantee an efficient and smooth course.
- Tools – technology, selection and use of appropriate support tools and their optimization to support the Lessons Learned process and its subprocesses.
- Training and education – the main sponsor activities needed to understand the importance of this process.

Figure 1: Components of the Lessons Learned System (NATO, 2016, p. 9)



The ceiling of this process is the very important sharing of information that represents the culmination of the entire Lessons Learned process. However, the most important are the cornerstones of the whole process, without which this process could not work effectively. The base of the Lessons Learned process is made up of commander's support – leadership, with senior military management knowing and understanding the benefits of the process. Then it is the commitment and thought of all involved. It is therefore necessary to achieve a state where all the participants will understand the importance of this process and, in addition, the support of the commander will be clear to all [8].

The goal of the lessons learned proces

The general objective of the Lessons Learned process is to preserve the organization's knowledge, is to transform the individual's experience into the knowledge of the organization so that other members of the organization can use their experience in the absence of the expert [5].

Therefore, using lessons learned can positively influence other processes of the organization on a continuous cycle of improvement.

Scheme of lessons learned process

The NATO Bi-Strategic Command Directive 080-006 describes the individual parts and sequence of the Lessons Learned process, which is then illustrated in Figure 2.

Observation

This is an identified problem that requires action to be taken to improve the status or best practice for reuse. These are precisely described facts, events, claims, statements that are based on the evaluation of information that describes a certain activity of units, immediate causes, effects or effects.

Knowledge can be Raw Observation, which requires further study or analysis to understand the cause of the event and to supplement the information, or the Mature Observation, to which there is sufficient information, or the cause of the event is known and is not needed its further study and analysis [5, 6, 7].

Analysis

It is a study of the whole through careful examination of its individual parts and their interrelationships [5, 6, 7].

For the purposes of the Lessons Learned process, it is about describing a given phenomenon, its causes and consequences, including the initial design of measures to prevent repetition of inappropriate practices or to make repetition of the appropriate ones.

Lesson identified

Identified experience because of knowledge analysis. In addition to describing the event, the causes and the consequences, it includes a proposal for remedial measures, concrete steps and responsibilities for implementing these measures [5, 6, 7].

Lesson learned

It is the result of the implementation of measures that have increased the ability of a particular element [5, 6, 7].

Knowledge

Newly generated information, whether in the form of knowledge, identified or generalized experience has an individual value for the user corresponding to his/her knowledge (5). Interpreting such information in interaction with experience, facts, individual value, thought processes, and meanings can be understood as knowledge.

Share

One of the most important part of the Lessons Learned process, which is intertwined with the process, is sharing. If NATO really wants to work based on a learning organization, it is necessary for individual Member States to share knowledge with others.

Database of knowledge and experience

In addition, to centrally store, manage, share, and access the knowledge, national and international databases have been created to enable registered users to easily access the information they need.

IMPROVING THE QUALITY OF MEDICAL SERVICES ACCORDING TO THE NATO MEDICAL LESSONS LEARNED PROCESS

First, quality in healthcare can be elusive and very complex in the military medical paradigm. The World Health Organization (WHO) defines the quality of health care as the extent to which health services provided to individuals and patient populations improve health outcomes [9]. For this purpose, healthcare must meet these key properties for all. It must be safe, efficient, timely, effective, and fair and focused on people – all activities must be driven by data and evidence based clinical practice. Health care quality can also be explained as a continuous improvement in the quality of health services provided, the ultimate goal of which is to improve health, improve the quality of life and satisfaction of the people they care for [10].

Thus, the Health Care Quality System includes the entire process of creating procedures, collecting information, setting clinical standards and assessing health care, health services and most importantly healthcare outcomes. It is also worth noting that a quality system is an intrinsically interconnected concept of quality elements that should help health organizations meet the goals of their mission [11]. In general terms, this applies to both civilian and military healthcare that the objective of a particular quality system in healthcare is always to improve the quality of health and related care provided in accordance with individual needs and patient requirements and is rooted in evidence and best practice. In military medical operations, duty of care for warfighters and deployed personnel is the burden of the countries involved and the alliance; this is extended to the combatants and civilian population as outlined in the UN and Geneva Conventions and international norms. This includes the provision of healthcare to all at a standard of care as close to and in keeping with clinical standards provided at peacetime found in the participating countries [12]. This is an extremely difficult task for the provision of medicine for deployed personnel in the dynamic environment that is war, conflict and peacekeeping in remote, austere and resource challenged environment.

APPLICATION OF LESSONS LEARNED PROCESS IN NATO MILITARY MEDICAL SERVICES

In October 2014, the NATO Center of Excellence for Military Medicine (MILMED COE) hosted the International Security Assistance Force (ISAF), the NATO-led security mission in Afghanistan, Medical Lessons Learned Workshop. This was performed in order to preserve the knowledge gained in ISAF and discuss health care expertise in ISAF in Afghanistan. Examples of the use of appropriate combat application tourniquets during severe limb bleeding have clearly shown that collecting knowledge and sharing Best Practices saves lives and improves the clinical outcomes of those injured on the battlefield. Additionally, on the basis of Lessons Learned from Afghanistan, there was a demand for safe removal by a light armored medical vehicle for evacuation purposes. The MEDEVAC (Medical Evacuation) system was also created based loosely on this process, which can skip individual stages of health care and from point of injury for the warfighter or enemy combatant to ensure they are appropriately evacuated as soon as possible directly to a Medical Treatment Facility (MTF) at a ROLE 2E or ROLE 3 facility.

A number of shortcomings have also been identified in the quality system of medical support; these are of special interest when making the entire system more robust, more resilient and capable of fighting the next battle with potentially different weapon systems and challenges than the current.

The results were presented to the Committee of Military Health Service Chiefs (COMEDS) at their 42nd session. At this meeting, it was decided that NATO MILMED COE would become the main contact and coordination center for the Lessons Learned process within the NATO military health service. Lessons Learned Process for NATO Health Support Centers is illustrated in Figure 3 [13]. In effect, the MATO MILMED COE LL has become the clearinghouse and central crossroads for all thing's best practices in NATO Military Medicine across the alliance.

By positioning itself as the coordinator and collector of observations and lessons, the Lessons Learned Branch of the MILMED COE adds value to the NATO system, processing and sharing Lessons and best practices for all members of the Coalition across the alliance. The LL Branch are building a roadmap to the future of the delivery of Health Support

Services through best practices and rooted in clinical evidence. The members of the alliance have delivered amazing health care, and we need to collect and share the Best Practices across the organization to ensure that everything that has been learned can continue to save lives, financial resources and sparse clinical resources [14].

Currently, the NATO MILMED COE Lessons Learned Branch is developing an inclusive process to improve the collection, processing, analysis, storage and sharing of military health-related knowledge. All the information presented and analyzed is uploaded and stored in the Library of Medical Lessons Learned MILMED COE Information and Knowledge Management (IKM), which is located on the MILMED COE website (http://www.coemed.org/medlldb). An important achievement from the third Medical Lessons Learned Workshop, which took place in 2015, was the establishment of the Multinational Medical Lessons Learned Team (MMLLT), where the Czech Military Medical Service is represented and hosted the second meeting as well. Participating countries agreed to share national information and documents related to military health through the MILMED COE IKM portal. The MILMED COE KM Portal is a good starting point for sharing across the alliance. Each contributing nation should decide on a national level what kind of document they would share. COMEDS has requested to rename the MMLLT, because this name is too similar and thus be confused with Medical Lessons Learned Core Team. With these changes, the new name of the body is Medical Sharing Group.

Moreover, the aim of the Medical Sharing Group is to establish the capability to share Lessons Learned information and knowledge across the Alliance [2]. Specifically, the Group members are responsible for reviewing Observations, Lessons Identified, and Lessons Learned information and knowledge within their national or organizational system and for forwarding any item to the NATO Medical Lessons Learned process that is considered beneficial to other Alliance Nations or to the Alliance as a whole. The intent is to empower the exchange of locally identified solutions or Best Practices with the goal of optimizing performance in current and future activities. The type and level of items to be shared will be established by the providing nation or organization and does not need to be the same for every participant. Additionally, the type and level of input provided by a participating entity does not have to remain the same over time and no formal process for change is required, enabling faster sharing of vital information [4]. The Medical Lessons Learned Process, an ongoing effort to improve process, is shown below in Figure 4.

Medical lessons learned conference on civilian – military interaction

A conference on civilian military cooperation has also been held several times. The main aim was to invite civilian and military organizations recently involved in Crisis Management, Humanitarian Assistance and relevant NATO, EU operations and share experiences, best practices and lessons learned. The last event was attended by 36 delegates from 12 nations and 13 organizations. A growing number of Crisis Management and Humanitarian Assistance missions/ events have been resulting in increasing demand for well-organized Civil-Military Interaction. Sharing individual perspectives on the situation and root causes of a crisis is the first step towards de-conflicting actions and complementing each other’s efforts, in effect to remove a duplication of effort. For the successful Civil-Military Interaction sharing of information is key importance to develop a common understanding about the situation and necessary measures.

Knowledge and tools of information collection

During the multinational medical exercise Vigorous Warrior 2017 a total of 391 pieces of observations were collected and analyzed. Five focus topics for further analysis were identified: Exercise Development, Interoperability, Patient Evacuation Coordination Cell, Bio-responsiveness and Experimentation [15]. Furthermore, a new tool for collecting and retrieving observations via smartphones was also introduced – the Observation, Discussion, Conclusion, Recommendation (ODCR) application, which was one of the tools for gaining knowledge (also those responsible for collecting knowledge - Office of Primary Responsibility (OPR) LL and paper and electronic forms). This application is fully functional in ANDROID and Apple´s iOS system (free download from Google play and AppStore). The previously mentioned Medical Knowledge Management Portal is a very important tool for preserving and sharing of observations and lessons. Today, there are over 1234 lessons from various areas of military and civilian health care (Exercises, Operations, UN, Ebola and others). Currently, the observations from the latest large-scale international medical exercise, Vigorous Warrior 2019, where 38 NATO and partner countries participated, are being analyzed within these new frameworks. The total number of primary findings is 464, of course, not all of the observations will be uploaded to the KM Portal avoiding repetition, and analysis will follow a standard approach.

DISCUSSION AND CONCLUSION

Evidenced-based medicine drives best practices. Knowledge sharing is an important prerequisite for the functioning and improvement of quality at all levels of healthcare within the deployment of medical units and medical teams across NATO operations. The quality of planning, which often takes place under time constraints and in a hostile environment, is improving and maximizes efforts across the NATO Alliance. The Lessons Learned (LL) process in clinical medicine for deployed and military support services drive the NATO Military Medical Center of Excellence (MILMED COE). This paper describes the Lessons Learned process and its use in NATO and partner countries medical services. Organizational learning drives development and progress and capturing lessons learned improves the quality of care in military medicine on a preventive, epidemiological, trauma, casualty evacuation and forward surgical care basis. The Lessons Learned process is an undertaking and an instrument that can also be used to achieve better international and civil-military cooperation. Lessons Learned process is one of the key elements of developing medical services in line with the changing operating environment.

Evolution of mortality rates in ST elevation myocardial infarction

Alice E. Munteanu[1,2], Cristina M. Calcan[1], Irina Florescu[2]

Abstract: *The purpose of this paper is to provide information about mortality rate in patients undergoing primary angioplasty for STEMI. Cardiovascular diseases lead to one third of the deaths worldwide, surpassing the mortality rate produced by neoplasia, acute respiratory failure and diabetes mellitus all together. In the world, approximately 17 million die annually because of cardiovascular disease and every 5 seconds one is suffering from a myocardial infarction.*

In 2010, in our country was implemented a national program (RO-STEMI) to offer rapid interventional treatment for patients with STEMI, aligned to ESC Guidelines. At the beginning only small parts of the patients were transferred to the hospital in charge for STEMI, so, we chose to study patients from the second year of the program and from last year. We made a retrospective study, including patients with STEMI that reached our hospital for primary angioplasty in the first 12h after the debut of the symptoms, aiming to make a parallel between the in-hospital mortality rates at maximum one month after the primary PCI. In order to be included, the patients must present ST elevation and another 1 out of 3 criteria (clinical, echocardiographic and biological changes suggestive for myocardial infarction).

The main target was to evaluate the evolution of early mortality rates post primary PCI after the changes in the ESC Guidelines and the progresses in the medical field. A secondary target was to correlate mortality rates with the presence of comorbidities or risk factors.

INTRODUCTION

Alexander Muirhead is reported to have attached wires to a feverish patient's wrist to obtain a record of the patient's heartbeat in 1872 at St Bartholomew's Hospital.[1]

Another early pioneer was Augustus Waller, of St Mary's Hospital in London.[2] His electrocardiograph machine consisted of a Lippmann capillary electrometer fixed to a projector. The trace from the heartbeat was projected onto a photographic plate that was itself fixed to a toy train. This allowed a heartbeat to be recorded in real time.

An initial breakthrough came when Willem Einthoven, working in Leiden, the Netherlands, used the string galvanometer (the first practical electrocardiograph) he invented in 1901.[2]

This device was much more sensitive than both the capillary electrometer Waller used and the string Galvanometer that had been invented separately in 1897 by the French engineer Clément Ader.[3]

Einthoven had previously, in

[1] Carol Davila University Central Emergency Military Hospital, Bucharest

[2] Titu Maiorescu University, Faculty of Medicine, Bucharest

1895, assigned the letters P, Q, R, S, and T to the deflections in the theoretical waveform he created using equations which corrected the actual waveform obtained by the capillary electrometer to compensate for the imprecision of that instrument. Einthoven also described the electrocardiographic features of a number of cardiovascular disorders. In 1924, he was awarded the Nobel Prize in Medicine for his discovery.[3] In 1937, Taro Takemi invented the first portable electrocardiograph machine.[4]

Cardiovascular diseases represent the main cause of death worldwide, 30% of them being caused by coronary artery disease. Myocardial infarction (MI) is one of the five main manifestations of coronary heart disease, namely stable angina pectoris, unstable angina pectoris, MI, heart failure and sudden death.[5]

Myocardial Infarction (MI) is defined by myocardial cell necrosis due to significant and sustained ischemia. Most frequently it is an acute manifestation of atherosclerosis-related coronary heart disease. MI results from either coronary heart disease, which implies obstruction to blood flow due to plaques in the coronary arteries or, much less frequently, to other obstructing mechanisms (e.g. embolism, spasm of plaque-free arteries).[6]

The clinical presentation of MI varies from a minor coronary event to life-threatening clinical situations or sudden death.[2] The criteria for STEMI are well known – specific, prolonged >15-20 min pain, specific site, and it is not ameliorated by nitroglycerin intake. The ECG shows persistent ST elevation or new onset of LBBB. Specific biomarkers are represented by high-sensitive Troponin I, CK/CK-MB, which have a specific dynamic curve.[7]

In 2010 in our country debutantes a national program named ”RO-STEMI”. In this program all patients with STEMI, from a well-defined area, are send to a certain hospital for being coronarographic evaluated. Due to this program more than 63% of patients’ beneficiated of myocardial reperfusion and the mortality rate dropped all over the country from 13 to 7%.[8]

MATERIALS AND METHODS

It’s been realized a retrospective study in STEMI patients in our hospital, on all patients from 2012 and 2016. All the patients included in this study respected STEMI criteria for diagnosis. We took 252 patients from 2012, out of which 29% were women and 71% were men, and 136 from 2016, with a non-significant difference in gender balance (28% women and 72% men). The number of patients is smaller in 2016 than in 2012 because in the beginnings of the national program there were only a small number of hospitals being part of it. In present the number of STEMI hospitals has increased so STEMI patients are distribute to more STEMI centers than during the past years.

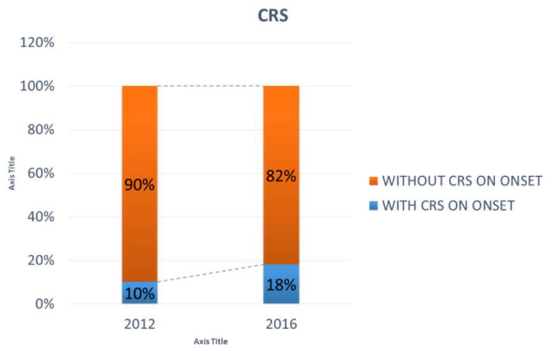
RESULTS

During this period of time, the median age of suffering an infarction was 60 years for men, with no significant difference between years, but for women the age evolved, so now, usually women suffer a myocardial infarction at about 63, compared with 66 years old in 2012.

The onset can be seen as a predictor for evolution and a gravity factor for STEMY patients.

A cardiorespiratory stop onset represents a high gravity risk factor. We noticed that in 2016 were twice more patients, than 2012, with cardiorespiratory stop on onset of STEMI. Knowing that, it is expected that the mortality rate being higher in 2016 that 2012.

Figure 1 Distribution of patients by cardiorespiratory stop onset.



The distribution of modifiable risk factors is the same for the 2 groups, the change consists of the number of risk factors present at the same patient, which was definitely higher last year (in average 2 risk factors per patient in 2012 vs. average 3.5 risk factors/patient in 2016). Even if we strongly advise the patients to quit smoking, and there is also a huge implication of the government in this, the number of smokers increased, but the good news is that their mortality has a decreasing trend over the years.

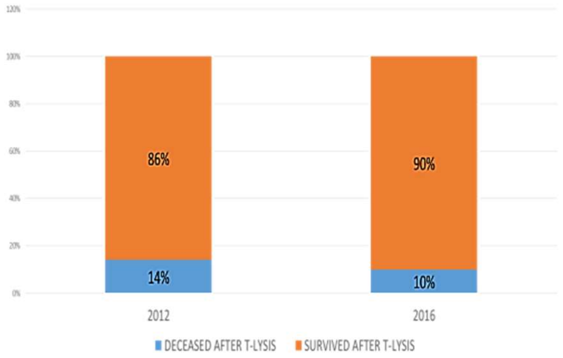
The median time from pain to cath-lab has lowered from 12h in 2012 to 9h in 2016. This improvement could be in one side due to well function of RO-STEMI program, and in other side due to improvement in social health education, the patients being better informed about myocardial infarction symptom-tology which decrease pain-call time.

If we take a look to the coronary lesions, we can see that first affected artery is left anterior descending artery (LAD), followed by right coronary artery (RCA), circumflex artery and marginal artery.

A very important observation is the growth of the number of patients with right coronary artery involvement, with can be associated with right ventricle infractions and an extremely poor prognosis. Also right coronary artery involvement means a higher risk of malignant arrhythmias and sudden cardiac death. 45% of STEMI patients had only one affected vessel, 40% had 2 affected vessels and only 15% had three coronary arteries affected most of them with CABG indication.

Only 15% of the patients in 2012 were thrombolysed before PCI, while in 2016 the use of t-lyse increase to more than 30% of the patients, this measure helps physicians to buy time for them to reach the cath lab.

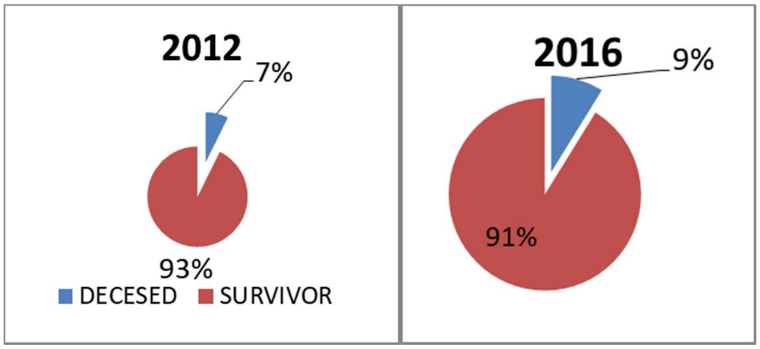
Figure 2 Rate of deceased after thrombolysis



From the number of those thrombolised, only a small amount has died, but none because of a bleeding. All died because of malignant arrhythmias or asystolia secondary to the myocardial infarction. Notice that in 2016, even though the number of thrombolised patients was bigger than in 2012, the rate of deceased patients after thrombolysis was smaller in 2016 than in 2012. The reason for this difference could be a better triage of elected patients and the evolution of thrombolytic agents.

At the beginning, drug eluded stents were extremely rare and expensive, nowadays we use much more frequently DES then bare metal stents, in 2016 73% of used stents were DES and the target is using only DES, as the indication in ESC guideline.[7] This made the rate of early in stent restenosis to go from almost 20% to 0%.

Figure 3 Mortality rate in the two groups of patients



Due to the shortening of the time from symptoms-onset to revascularization and from associating more frequently thrombolysis with PCI, the number of those with ventricular dysfunction has dropped significantly.

Even though the number of thrombolysis raised, and the time to cath lab is shorter, the number of patients who didn`t make it to the cath lab is increasing, the mortality rate has increased from 2012 to 2016. If we consider that the rate of cardiorespiratory stop as onset as a high gravity factor and if we see that the patients in 2016 were more complex than in 2012, then the high mortality rate is expected. Another factor suggests that the gravity of cases was higher in 2016 is that the number of deceased patients without reperfusion was higher in 2016.

CONCLUSIONS

The National Program RO-STEMI became more effective by increasing the number of involved hospitals.

During time the mortality rate have had a slightly increasing trend due to a growth of the number of risk factors/patient, an increase in the severity of the coronary lesions, an increase in the number of the lesions in the right coronary artery, and a poorer prognosis in echocardiography.

The time from symptoms onset to cath lab decreased and by associating more frequently thrombolysis for “buying” more time, so the chances for the ventricle to remodel remain low.

By respecting the ESC guidelines for each period of time, even though the early mortality rate seems to have an ascending trend, the overall mortality rate and longtime prognosis of the STEMI patients are getting better.

It is very important to make such an analysis from time to time, in order to make thinks go better and see where some changes could be made.

Exploring of clinical decision making in care of patients with acute care in critical nurses: A qualitative content analysis

Mohammad Aghajani[1], Neda M. Ajorpaz[2], Mohsen Taghadosi[3]

Abstract: *The appropriate clinical decision-making of the nurses can improve the patient outcome and reduce costs, otherwise delaying the recovery and preferably the death of the patient especially in acute care setting. The aim of this study was to describe the clinical decision making in care of patients with acute care in critical nurses.*

This study was a qualitative study conducted in 2020. Purposive sampling was used and continued until saturation. The study involved sixteen semi-structured interviews were conducted with critical nurses who had experience providing care for acute patients in critical care units. Interviews transcript and analyzed by qualitative content analysis. Two major themes were generated from the data included instantaneous decision-making and life-saving of the patient. This process was depended on the nurse's ability to summarize in the moment, to consider everything, to focus on the patient, to combine experience and knowledge, to concern the patient's life, to prevent the deterioration of the patient's conditions and responsibility to their patients.

Keywords: *clinical decision making, acute care, critical nurses, COVID-19*

INTRODUCTION

Clinical decision making (CDM) is a fundamental phenomenon in healthcare practice. While CDM influences the entire range of healthcare practitioners, nurses, as frontline clinicians, are faced with important clinical decisions on a daily basis [1, 2].

The appropriate decision-making of the nurse can improve the patient and reduce costs, otherwise delaying the recovery and preferably the death of the patient [3]. Based on studies, it is identified that up to 98,000 patients die each year as a result of poor decision-making in healthcare [4]. Also research shows that not making the right decision in a timely manner can prolong the treatment process and the situation of patients [5]. 4% of patients admitted to hospitals in the United States, about 16% and 6% in Australia and the United Kingdom have suffered injuries such as permanent disability and death due to lack of proper decision-making. While the right and timely decision making, team working and effective communication between staff can reduce half of these injuries [6].

Rapid and appropriate decision-making is a need of organizations and hospitals. However, complex issues surround the decision-making process, such as the past experiences, values, beliefs, skills and technical knowledge of the decision maker [7].

CDM in nursing is frequently based on two styles of thinking: analytical and intuitive thinking. Analytical thinking is a logical style of thinking based on objective data. Intuitive thinking is driven by intuition and experience [8]. In life-threatening conditions and crises, as well as situations wherein there is a need for creativity and innovation, nurses use intuition in their decision making. Therefore, in critical health conditions, CDM is essential for nurses to improve quality of care, manage crises, and diagnose patients'

conditions, as well as to help reduce mortality rates [9].

Currently, nurses around the world are dealing with COVID-19, a disease that continuously demonstrates a variety of unknown and newly-known features. The global COVID-19 mortality rate is between 3% and 15% [10]. In this condition, due to lack of knowledge and clinical guidelines, nurses CDM have a vital role in managing the outcome of the disease and the health of clients. Decision-making in critical care nursing is a complex process [11]. Nurses must consider numerous, potentially competing factors when making decisions to meet patient and family needs [2]. This process is further complicated by the fact that nurses may care for five or more patients in a critical care unit [2]. The nurse's decision making in critical care is highly demanding, while critical nurses make a clinical decision almost every 30 seconds [12].

Therefore the question is how do nurses make decisions in acute situations. A better understanding of decision-making research in this context can help to guide future efforts to support nursing practice. Therefore, this study explores the experience of clinical decision making in care of patients with acute care in critical nurses.

METHOD

The present study was a qualitative descriptive study which was conducted to explore the clinical decision making in care of patients with acute care by critical nurses in 2020. Content analysis is a research approach for making inferences from data to their context, with the purpose of providing new insights, knowledge and the representation of the facts [13]. Qualitative content analysis as a research method provides an instrument for making inferences from data to their context [13], and in this process, the textual data explored and interpreted using the systematic coding process [14]

Participants and sampling

The purposive sampling was conducted among nurses who were providing care for patients in critical care units including the intensive care unit (ICU) and Emergency Departments (ED) of subspecialty Hospital of Kashan University of Medical Sciences. This comprehensive hospital allocated to care of COVID-19 patients. The inclusion criteria included the working experience in critical care units at least for two years and willingness to participate in the research. The exclusion criterion was reluctant to continue the study. The first participant was a nurse with independent and fast decision maker in the research setting, which had recommended by three nursing managers and was interested to speak about his experience.

Sampling continued until data saturation was done. Data saturation was identified through repetition of the participants' data in the interviews and that no new content is obtained [15]. In our study saturation occurred after interviewing with 16 participants.

Data collection

Prior to initiating interviews, main researcher was attempted to obtain the collaboration of the participants by creating a trust-based environment, explaining the aim of the study and ensuring the confidentiality of information. The data was collected with semi-structured interviews at the time and place that was appropriate for the participants. The process of interviewing initiated with open-ended questions based on the aim of the study. All interviews were recorded (Table 1).

Table 1: Interview techniques for data collection

Researcher activity
Introducing myself and the purpose of the study
Explaining the content of the consent form and answering the questions
Obtaining a verbal agreement and signing the consent form
Starting the voice recorder
Starting the interview with general open-ended questions such as: How do you make a clinical decision making in a critical situation? Would you please tell me about how do you of intuitive decision making in the care of COVID-19 patients? Would you please tell me about your experiences of clinical decision making for a COVID-19 patient without documentation? What conditions have you encountered in bedside that has caused you to use intuition? Please explain.
Asking for example: Please give me an example of your clinical decision making. Using active listening techniques: Eye contact, silence, head nods, use of statements such as "OK I see…". Watching for non-verbal cues: eye contact, facial expressions, tone of voice, gestures …
Using probing questions: Please tell me more about that. What else can you remember about that situation? Can you think of another example of this? What Exactly did you say? I'd be inspired.
Get more details: Tell me more about that. Can you tell me more about that?
Clarifying what the participants said: Please say what you mean by…. When you say … what are you actually doing or feeling? So you are saying...?
Summarizing the interview: It sounds like you are saying, "...". Is that a fair summary?

The participants were asked to discuss what they experience and understand as nursing CDM in moment in critical unit. The interview guide included the following questions:

- How to make clinical decisions in critical situations or acute care? Please explain your experience in this field.
- Why/how did you make such a clinical decision making?
- what are you actually doing or feeling?
- Tell me more about that. Can you tell me more about that?

Interviews were held in a private room, so that the privacy of the people was respected. The room was disinfected before and after each interview. The interviewer and the participant wore masks and gloves, and at least one meter separated the interviewer and the participant to observe social distancing.

The interview took between 40 to 80 minutes depending on the participants' circumstances. The interviews were conducted in Persian and analyzed and the results were translated into English only in the final report. The conversations were recorded on the audio file and then transcribed immediately.

Data Analysis

The transcribed interviews were analyzed through qualitative content analysis method following an inferential approach. The process of organizing the qualitative data in inferential content analysis included open coding, abstraction, and creating categories [16]. Elo and Kyngas pictured inferential categorization plan in qualitative content analysis [13]. Data analysis and data gathering were conducted simultaneously. Coding and classifying themes were done by the researchers

Trustworthiness

To ensure the trustworthiness of this qualitative research, confirmability, credibility, dependability, and transferability were established [17]. We used rewriting, member check, reviewing texts and using the participants' own words, monitoring translations, recording audio, the conducting of interview, coding, themes and sub themes and using of direct quotes to support the findings.

The researcher used an adequate amount of time to collect comprehensive data. The researcher informed them about the objectives, and established trust with participants throughout the interview and providing feedback to the research team for further interviews. We employed the MAXQDA 10 software for data management.

Ethical considerations

The study was approved by Ethics Committee.

The participants were informed about the study's objectives and consent form was obtained from all participants.

RESULTS

The participants were 16 critical nurses. Ten participants were women. Their nursing experience ranged from 4 to 25 years, and their academic degrees consisted of bachelors, masters, and Ph.D. (Table 2).

Table 2: Baseline characteristics of participants (n=16)

Contractual	8 (50)	

Based on data analysis, 362 primary codes, 7 subcategories, and two categories emerged (Table 3).

Table 3: The themes and subthemes of nurses caring for acute patients.

Themes	Subthemes
Instantaneous decision-making	Summarizing in the moment Considering everything Focusing on the patient combining experience and knowledge
Life-saving of the patient	The importance of the patient's life Deterioration of the patient's conditions Responsibility

From the point of view the participants and based on their experiences, the CDM of critical nurses had two major characteristics:

1. instantaneous decision-making (summarizing in the moment, considering everything, focusing on the patient, combining experience and knowledge) and

2. life-saving of the patient (the importance of the patient's life, deterioration of the patient's conditions, responsibility).

Instantaneous decision-making

Almost all nurses stated that they made instantaneous decisions in the face of critical situations, especially those where the patient's life was in danger. This DSM seems to be intuitive because it does not have the linear and logical features of evidence-based decision making.

A participant (P3) stated, “In a night shift, there was a 30-year-old patient in respiratory distress. I had an inner sense indicating that the patient’s health conditions would quickly deteriorate. I begged the physician, explaining that this was an emergency... there’s going to be a need for endotracheal intubation... we must intubate the patient right now. The physician said there was no need for intubation at the moment, and we needed to monitor the patient to see if the patient’s conditions would change. After a short while, the respiratory distress worsened very quickly, and the patient passed away. Unfortunately, we did not have the chance to intubate the patient and start mechanical ventilation on time. Later, the physician told me I was right...we should have intubated the patient sooner.” Indeed we see the perception of the inner sense, followed by anticipation and pursuit, and the inner revolution in the intuitive decision making.

Summarizing in the moment. Ten participants indicated that in critical situations in a short period of time, everything quickly summarized in their minds. In fact, at the critical moment and before the action, they summarized and concluded what they were receiving from the patient's signs and symptoms at the moment.

One participant (P15) said “….Everything is summed up in your mind until you decide what to do at that moment….”

Considering everything. Nine participants indicated that they unconsciously considered all conditions, possibilities, prognosis, and possible consequences for the patient.

The participant (P11) said: “A patient with a chest pain was brought to the emergency department by 115, I unconsciously compared and adapted all the patient conditions in my mind and I guessed the possibility of a heart attack that was happened.” Another participant pointed: “I consider the patient's history and prognosis, for example, that she had a history of heart disease based on my experiences.”

Focus on the patient. About half of the participants reported that when caring for acute patients, their minds were constantly engaged with the patient during resting and working time, and they focused on patient.

One participant (P4) reported “….even I thought about my patient while resting in the department”. Another participant believed that “I kept telling myself if something bad is going to happen what I should do, hence, I went to the patient's bed and by the way something happens to her at that moment”. Another participant indicated “…. concerned about my patient until morning”.

Combining experience and knowledge. Fourteen of the 16 participants reported combining their previous knowledge and experience in acute patient conditions. A participant stated, “In MI patients, I have seen that their skin color changes to whitish and blackish colors. Many COVID-19 patients also show these changes before a heart attack. In fact, I was reminded of previous experiences and the things that had read previously in books and combined them.” (P1).

Life-saving of the patient

Almost all the participants expressed reason for the CDM in patients with acute care were to save the patient's life. Participants indicated that the life-saving of the patient was a priority for them. The nurses believed that even if decision making was not in accordance with the usual and legal process of unit, but they did it if it was necessary to save the patient's life.

Some participants compared the COVID-19 condition to a battlefield. “I feel like I’m in a battlefield. When you have seven cases of death in just a few hours, you believe whatever you do, even if not necessary, might save your patient’s life.” (P5).

The importance of the patient's life. Participants considered life-saving of the patient to be the most important blessing from God and lack of appropriate and immediate clinical decision-making in critical situations was equated with patient loss.

“For me, the patient’s life is the priority. If I feel confident something is critical for the patient’s life and health, I will definitely do it”. (P8). Another participant indicated “…receiving Pack cell are very important for the patient and may save patient life”.

Deterioration of the patient's conditions. The participants reported that due to the importance of golden time in patients in critical situations, decision making is very important and lack of timely decision making will deteriorate the patient's conditions.

“I experienced in ICU that you put your hand on the patient and you see that it is cold, that is, lack of heart pulse needs 3 to 4 hours of care. So if we do not do something worse, we have to make a timely decision”. (P7)

Another participant considered the heavy workload and the related tensions as factors for relying to their clinical decisions. “Everything was novel. The whole staffs were feeling the same and were stressed. You felt extremely concerned about worsening your patients’ conditions. In these conditions, you feel like you have to trust your decisions.” (P5)

Responsibility

Almost all participants believed that they were responsible for their conscience, professional responsibility, patients, religious beliefs and society.

. “A sense of responsibility did not leave me alone. Based on your conscience, you feel responsible to do your best for your patient” (P15).

“To some extent, it is a kind of feeling of responsibility... About the COVID-19 crisis, we feel we are responsible for patients in all aspects.” (P3). Another participant (P7) believed that patients benefit from nurses’ decision making. “I felt like it was better for the patient to get discharged and go home. A hospital environment in this situation is not safe for the patient.”

DISCUSSION

Clinical decision making is a main role of professional nurses [18]. This study was conducted to clarify the clinical decision making in care of patients with acute care in critical nurses and two themes were categorized as the main characteristics for a critical nurse including "instantaneous decision-making" and "life-saving of the patient".

On the first category that emerged in the results, in the acute conditions of the patient, in which time plays an essential role in saving the patient, the CDM of the nurses and subsequent treatment-care actions are very important. CDM distinguishes the professional nurse from the non-professional care staff [18]. Critical nurses decided by focus on patients and considering everything related to their patient, then they summarized data in their mind and cared of the patients with integrating experience and knowledge. The research show that each nurse uses to make a decision depends more on the type of task and the field conditions than on her knowledge and experience [19-21]. In the other hand, effective decision-making requires a combination of knowledge and skills and close communication with the patient for a deep understanding of the situation, which has been interpreted by some authors as "seeing the holistic view" or "deep understanding of the clinical view" [22-24].

Two categories show that the most important item for deciding in a patient's acute conditions is life saving of patient. The participants in this research indicated that they make decision because of the importance of the patient's life and responsibility towards their conscience, profession, society and in order to prevent from worsening the patient's conditions. Other studies in intensive care unit nurses confirm these finding [5,11,25,26].

Overall, based on the findings and features extracted, CDM in acute care settings seems to be more intuitive than analytical. Today, in health novel and complex conditions, this type of decision-making has become even more important because of the care of patients with COVID-19. Recently, the use of intuition in the process of caring for the psychological aspect and its effects on decision-making has become a favorite subject for health researchers [11,22,27].

CONCLUSION

The findings of the study described how and why critical nurses in acute care made clinical decisions. Indeed critical nurses by instantaneous decision-making save life of the patient and prevent the deterioration of the patient's conditions. Nurses tried to provide the best outcomes of care and treatment through analytical and especially intuitive model in acute situations. This CDM was dependent on the nurse’s ability to summarize in the moment, to consider everything, to focus on the patient, to combine experience and knowledge, to concern the patient's life, to prevent the deterioration of the patient's conditions and responsibility to their patients. These findings can provide the basis to promote competency and practical guidelines for clinical nurses and health managers.

Extra-pulmonary tuberculosis in immunocompetent patients: Case series and mini review of the literature

Valeriu Gheorghiță[1,2], Adelina M. Cosma Radu[3], Ana C. Ciobotaru[3], Ion Ștefan[2,4], Claudiu G. Socoliuc[5], Laura Bălănescu[1,6], Florin A. Căruntu[1,3]

Abstract: *Introduction: Tuberculosis (TB) is still one of the most frequent infectious diseases, causing 2 million deaths a year worldwide. The prevalence of TB has increased in both immunocompetent and immunocompromised and virtually, it can affect any organ. Up to 25% of tuberculosis cases present extra-pulmonary involvement. The diagnosis of extra-pulmonary TB (EPTB) is difficult, often requiring biopsy.*

Material and methods: We present two cases of EPTB in immunocompetent young women. The first case is about a 15-years old female who presented with persistent high fever, ascites and an increased CA-125 serum level. Biochemical analysis of ascites fluid revealed a high value of adenosine deaminase (ADA), negative Ziehl-Neelsen stain and undetectable Mycobacterium tuberculosis at PCR assay. The peritoneal biopsy confirmed the diagnosis of peritoneal TB. The second case, a 29-years old female with a seven-month history of cervical lymph nodes swelling, with drainage and excision biopsy performed, misdiagnosed as cats-scratch disease based on the histological description as granulomatous lymphadenitis, which turned out to be tuberculous lymphadenitis at the second histopathological opinion.

In conclusion, these cases highlight the need for tuberculosis consideration in the differential diagnosis of extra-pulmonary involvement, even in immunocompetent individuals, in order to decrease the misdiagnoses and complications rates.

Keywords: *extra-pulmonary tuberculosis, immunocompetent, peritoneal tuberculosis, lymphadenitis, challenging diagnosis*

INTRODUCTION

Tuberculosis (TB) can be considered an ancient disease which is still causing 2 million deaths a year worldwide. According to global statistics, one person is newly infected with TB bacilli every second world-wide and one third of the global population is currently infected with TB. TB ranks alongside HIV as a leading cause of death from an infectious disease. The prevalence of TB has increased in both immunocompetent and immunecompromised and virtually, it can affect any organ.

It is now seen that extra-pulmonary presentations form a major proportion of new cases. Between 2002 and 2011, extra-pulmonary TB (EPTB) accounted for 19.3% of all TB cases throughout Europe. EPTB is more common in children, women and minorities. Based on Romanian Tuberculosis Notification Data,

[2] "Dr. Carol Davila" University Central Emergency Military Hospital, Bucharest

[3] "Prof. Dr. Matei Balș" National Institute for Infectious Diseases, Bucharest

[4] "Titu Maiorescu" University, Faculty of Medicine, Bucharest

[5] Colentina Clinical Hospital, Pediatric Dermathology Department, Bucharest

[6] "Grigore Alexandrescu'' Emergency Clinical Hospital for Children, Bucharest

12,498 new TB cases (a rate of 6.4 cases per 100,000 individuals) were registered in our country during 2014, which is higher compared with a rate of 5.2 cases per 100,000 individuals throughout Europe. Extra-pulmonary involvement occurred in 8% of the new cases. Among the extra-pulmonary TB (EPTB) cases, 30.1% were lymph node TB, 13.3 % osteo-articular TB, 6.3% genitourinary TB and 47.3% in other anatomical sites.

Lymphadenitis is the most common extra-pulmonary presentation of TB. Abdominal TB is also one of the most prevalent forms of EPTB. In particular, peritoneal TB is the sixth most common location of EPTB, with an incidence between 0.1% and 0.7% of all TB cases worldwide.

In EPTB, the diagnosis is challenging because of nonspecific symptoms and low sensitivity of classical diagnostic methods, such as microscopy and culture and it is often requiring biopsy. Delay in diagnosis and treatment initiations lead to poor prognosis and sequelae in up to 25% of cases.

MATERIAL AND METHOD

Case 1

A 15-year-old young female patient presented at the territorial hospital with abdominal distension, low abdominal pain, fever (40 degrees) with shiver, excessive sweating and loss of appetite. No other previous health problems were reported. All vaccines provided in universal vaccination schedule were performed. She denied smoking, drug use or alcohol consumption, and she was sexually inactive. The tests performed led to the diagnosis of ascites of unknown etiology. Despite the empirical antibiotic treatment with ceftriaxone, she continued to present fever, being subsequently referred to our clinic for further investigations.

At admission, the clinical status of the patient revealed a relatively good general condition, without fever, no abnormalities on pulmonary examination and normal vital signs. The abdomen was enlarged, with shifting dullness and positive ascitic wave, diffuse pain on palpation, without signs of peritoneal irritation. No masses or organomegaly were present on clinical examination. Blood tests showed lymphopenia (880/mm^3), mild microcytic anemia, elevated inflammatory markers (erythrocyte sedimentation rate of 58 mm/1h, Fibrinogen of 709 mg/dl, C-reactive protein of 112 mg/dl) with negative procalcitonin and normal biochemistry. Chest X-ray did not reveal any infiltrates. Abdominal ultrasonography showed the ascites in large quantity. Transthoracic echocardiography described minimal pericardial effusion (20-30 millimeters).

Further immunology and virology lab tests [rheumatoid factor, antinuclear antibodies, anti-double stranded DNA antibodies (Ab), complement fractions C3, C4, hepatitis B surface antigen, hepatitis C virus Ab, and Human Immunodeficiency Virus 1 and 2 Ab] were negative. The patient underwent paracentesis with ascitic fluid analysis. The gross appearance of the fluid was pale yellow, with exudative features, based on the biochemistry, a total nucleated cell count of 600/mm3 with predominance of polymorphic lymphocytes (72%). The ascites fluid ADA level reached a high value of 140 IU/l, normal value being <33 IU/L. The microscopy for non-specific bacteria and acid fast bacilli, using Gram and Ziehl-Neelsen stains, was negative. Moreover, we performed a broad-spectrum molecular microbial identification from the ascites (IRIDICA BAC BSI® Assay platform for bacteria and fungi) and MTB-DNA amplification (GeneXpert® platform), both of them being undetectable. The serum tumor markers such as CEA, CA19-9 and CA15-3 were within normal limits, apart from CA 125, which was significantly higher (189.5 IU/ml). Serum gamma-interferon specific to MTB antigens produced by T cells (QuantiFERON®-TB Gold) was positive.

In the meantime, we started empiric antibiotic treatment based on oral clarithromycin 1g/day for 3 days, with fever persistence. Then we switched to intravenous (iv) ertapenem 1g/day. After 5 days of ertapenem treatment, the fever has disappeared, with minimal ascites fluid regression. Abdominal and pelvic magnetic resonance imaging (MRI) showed the presence of ascites and described irregular masses with peripheral contrast enhancement near the ovarian fossa, similarly to epiploic fringes.

The patient was transferred to a pediatric general surgery department for exploratory laparoscopy and peritoneal biopsy. The laparoscopic findings described thickened peritoneum with disseminated miliary white nodules on the surface and intestinal wall congestion, being highly suggestive of PTB (Figure 1).

Figure 1. Laparoscopic findings with thickened peritoneum, diffuse congestion, disseminated milliary white nodules on the surface of peritoneum highly suggestive for TB.

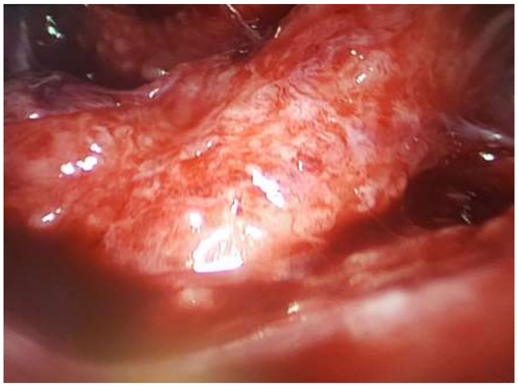

Figure 2. Multiple foci of granulomatous inflammation with multinucleated giant cells, epithelioid histiocytic cells and peripheral lymphocytes are seen on Periodic acid-Schiff (PAS) staining (100X).

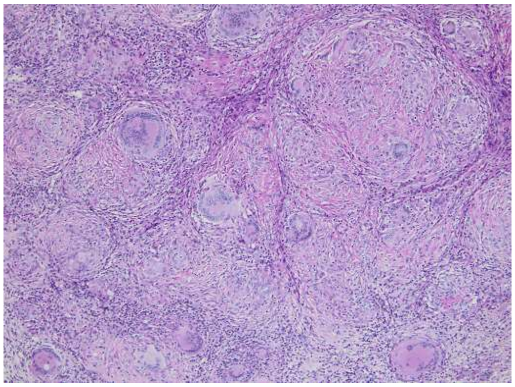


Multiple tissue biopsies were collected. Based on clinical and biological features, along with laparoscopic findings, we decided to start antituberculous therapy with isoniazid 200 mg, rifampicin 450 mg, pyrazinamide 1,500 mg, ethambutol 1,200 mg daily, and oral pyridoxine vitamin 250 mg/day. After 10 days of antituberculous treatment, the symptoms of the patient have regressed, serum C-reactive protein level decreased from 153 mg/dl to 8.6 mg/dl, with no ascites presence at the abdominal ultrasound.

The histopathological results confirmed the diagnosis of peritoneal tuberculosis (Figure 2). In addition, MTB-DNA from the biopsy sample was detected, with no detection of genetic mutations associated with rifampicin resistance.

Case 2

A previously healthy, 30 year-old Caucasian female, smoker (10 pack/year), presented to our department for laterocervical and supraclavicular lymph nodes enlargement, slightly painful on palpation. She also complained of fatigue and dry cough. She was not on any medication, no histories of allergies, all vaccines provided in universal vaccination schedule were performed and she has not travelled during the past year outside of Romania. She has a cat which is an indoor pet.

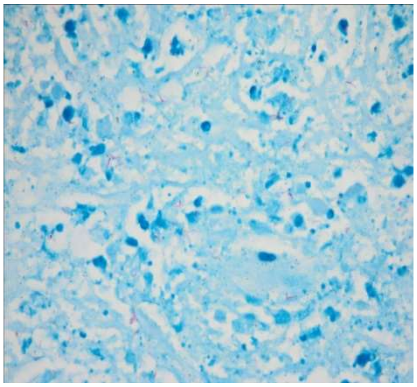
The symptoms began about 7 months ago with a red, painful swelling of about 4-5 cm, in her left laterocervical region, which she noticed several weeks ago and continued to enlarge. She went to the surgical department where was performed the incision of the lymph node with drainage and lavage. The cultures provided from the procedure were sterile at 48 hours.

5 months later, she presented to the thoracic surgery department with suppurated supraclavicular lymph nodes. All the laboratory tests performed were normal (blood count, coagulation, biochemistry (glucose, creatinine, ALT, AST, GGT, Alkaline phosphatase, sodium, potassium). The patient was evaluated by cervical and thoraco-abdominal CT and the images showed multiple extended outbreaks of pulmonary infiltrates with tree in bud pattern in the apical-dorsal segment of the superior left lobe and in the dorsal segment of the superior right lobe and some isolated centimeter nodal images and mediastinal, supra-clavicular, and bilateral laterocervical lymph nodes. They continued the investigations with bronchoscopy with GenExpert test, direct microscopic examination and culture for acid fast bacilli in bronchial aspiration and sputum. They performed an excision biopsy of the supraclavicular lymph node and the histopathological findings described as confluent epithelioid granulomas

with central clotting necrosis have been interpreted as specific lesions for cat scratch disease. The patient was referred to a department of infectious diseases for additional investigations and specific treatment. Meanwhile, the GenExpert test and the direct microscopic examination for acid fast bacilli were negative with cultures in progress.

When she came in our department, she had good general state. On physical examination we noticed in the left laterocervical area two scars with redness surrounding and several firm, tender, lymph nodes about 1 to 3 cm in diameter, palpable in the left laterocervical and supraclavicular area. The initial laboratory tests were normal, the test for antibody to human immunodeficiency virus (HIV) was also normal, with no other immunity issue found. The serology for Bartonella henselae infection was negative for both antibodies Ig M and Ig G. The patient was referred to the National Institute of Pneumophtisiology for reevaluation. Based on the high clinical and histopathological suspicion of tuberculosis, the biopsy blades were re-analyzed and by performing Ziehl-Neelsen coloration, were discovered few acid-fast bacilli (Figure 3). The histopathological description with necrotizing granulomatous epithelioid inflammation was also pathognomonic for tuberculosis.

Figure 3. Acid-fast bacilli on Ziehl–Neelsen smear (100X)



The patient was put on anti-tubercular drugs with good evolution. The cultures for mycobacterium tuberculosis read at 2 months were positive.

DISCUSSIONS

TB is still one of the most frequent infectious disease and worldwide strategies to eradicate it have met only with partial success. According to global tuberculosis report, in 2015, there were an estimated 10.4 million new TB cases worldwide, of which 5.9 million (56%) were among men, 3.5 million (34%) among women and 1.0 million (10%) among children. People living with HIV accounted for 1.2 million (11%) of all new TB cases. There were an estimated 1.4 million TB deaths in 2015, and an additional 0.4 million deaths resulting from TB disease among people with HIV. Although the number of TB deaths fell by 22% between 2000 and 2015, TB remained one of the top 10 causes of death worldwide in 2015.

Although it is well known that TB occurs mainly in immunocompromised host, it seems that the prevalence of TB has increased both in immune-competent and immunocompromised patients. Nowadays extra-pulmonary presentations form a major proportion of new cases of TB. Among them, lymphadenitis is the most common clinical presentation, with a major predilection for cervical lymph nodes.

Abdominal TB is also one of the most prevalent forms of EPTB and the peritoneal involvement has been observed in about 1-2% of all cases of TB. Pelvic TB is common in developing countries, mainly in young, fertile women aged between 15 to 25 years old. The common clinical features include ascites, fever, diffuse abdominal pain and weight loss. Therefore, peritoneal TB is often misdiagnosed, usually as carcinomatous peritonitis. The lacking of medical awareness of pelvic TB could lead to mutilating surgical treatment like adnexectomy for many young, fertile, women.

Our patient presented with a clinical picture highly compatible with peritoneal TB. However, we had to continue the investigations because the conventional methods, like microscopy and MTB-DNA amplification from ascitic fluid, failed to establish the positive diagnosis. In addition to clinic-biological findings and radiological characteristics, the accuracy of early diagnosis was increased by measuring the ascites ADA and serum CA125 levels.

The studies showed a significant correlation between

ADA and CA-125 in patients with peritoneal TB. The tests are simple, non-invasive, cheap, and it seems to have enough power to confirm or exclude the diagnosis of peritoneal tuberculosis and it is a good approach to begin the empirical treatment while waiting for the histopathological result or cultures.

The diagnosis of peritoneal TB can also be suggested by characteristics findings at laparoscopy or laparotomy; however, these are invasive examination methods and should be recommended with caution in clinical practice.

Lymphadenitis is the most common extra-pulmonary presentation of TB. It is seen in nearly 35 per cent of extra-pulmonary TB which constituted about 15 to 20 per cent of all cases of TB. Although previously considered a childhood disease, lymphadenitis has a peak age of onset of 20-40 years. The most common site of involvement is represented by cervical lymph nodes, reported in 60% to 90% patients, followed by mediastinal and axillary lymph nodes6.

Cervical lymph nodes can be involved via various pathological processes, including inflammatory diseases, lymphomas and even metastases. It is important that a high index of suspicion for tuberculous lymphadenopathy should be kept in mind because it mimics other pathologic processes and yields inconsistent physical and laboratory findings.

TB lymphadenitis usually presents with gradually painless swelling of one or more lymph nodes. Initially the nodes are firm, mobile, later they become matted with inflamed overlying skin and with abscesses formation in the advanced stages. Some patients may associate systemic symptoms such as fever, weight loss, fatigue, dry cough.

In our case, the patient had a seven-month history of cervical lymph nodes gradually swelling, which become matted with redness of the overlying skin. She also associated systemic symptoms represented by dry cough and fatigue.

The diagnosis of tuberculous lymphadenitis is difficult due to low sensitivity of mycobacterial isolation, prolonged time of the isolation process and multiple differential diagnosis that need to be ruled out. In endemic areas, for faster diagnosis, has been used fine-needle aspiration cytology (FNAC), combined with polymerase chain reaction for detecting Mycobacterium tuberculosis, in the absence of compatible cytological findings or negative acid-fast bacilli smears. Acid fast bacilli may be present in 25-50% of smears and the mycobacterium may be isolated in up to 70% of cases where there is a high suspicion of tuberculosis. Caseating granulomas are seen in almost all the biopsies and in 77% cases of the FNAC's. Typically, epithelioid cell granulomas, multinucleated giant cells and caseation necrosis are features of tuberculous lymphadenitis but these are neither specific nor sensitive and the diagnosis remains a challenge, necessitating a high index of suspicion, since granulomatous lymphadenopathy has an extensive differential diagnosis [13].

Cat scratch disease (CSD) is an infectious disease caused by gram-negative bacteria Bartonella henselae (B. henselae) and/or Bartonella quintana. It is represented by regional suppurated lymphadenitis, the lymph nodes affected are cervical (33%), axillary (27%) and inguinal (18%). The disease affects children and youths under 18 years old. Epidemiologic studies from the United States, Europe, Israel, Australia, and Japan, suggest that CSD has a worldwide distribution. In the United States, a retrospective study of patients younger than 65 years of age identified 13,273 patients with a diagnosis of CSD from 2005 to 2013. The diagnosis is based on the following: a) history of contact with a cat; b) checking of injury sites; c) regional lymph node swelling; d)characteristic histology of lymph node; e)skin test for CSD, replaced in the last years by immunohistochemically staining with antibodies to B. henselae in formalin-fixed paraffin–embedded tissue sections and polymerase chain reaction.

The histopathologic findings are nonspecific and depend upon the stage of the disease. Lymphoid hyperplasia is present initially, followed by the development of stellate granulomas. The centers are acellular and necrotic with histiocytes and peripheral lymphocytes surrounding these areas. Microabscesses develop and may become confluent at a later stage. Although these findings support a diagnosis of CSD, they should not be considered definitive.

Based on the granulomas found on the histological examination, our patient was first misdiagnosed as cat scratch disease without staining for acid-fast bacilli or PCR identification for Mycobacterium tuberculosis on the biopsy specimens.

CONCLUSIONS

Tuberculosis still remains a worldwide public health issue. It is still a common disease in developing countries, even in immunocompetent individuals. It should be kept in mind in the differential diagnosis of extra-pulmonary manifestations in order to avoid misdiagnosing and further complications. Surgical biopsy leaves unwanted scars, causing esthetic problems and also the possibility of long-term drainage problems through the incision line.

In young, fertile, women, presenting with febrile ascites, often mimicking adnexal malignancy, surgeons should be aware of peritoneal TB, avoiding unnecessary mutilating surgery leading to increase complications, such as infertility.

Facial skin cancer: our surgical experience

Adrian Alexandru[1,2], Ana Maria Oproiu[1,2], Anamaria Grigore[2], Ioana M. Dogaru[1,2], Minodora Onisai[1,2]

Abstract: *Skin cancer represents an important part of the plastic surgeon's practice, and surgical excision followed by reconstruction is the most frequently used procedure. The main objective of this paper is to report and evaluate our experience in the treatment of facial nonmelanoma skin cancer.*

Method. The study is based on 303 patients who were diagnosed with facial malignant tumors, between 2004 and 2015, in the Plastic and Reconstructive Surgery Clinic, Emergency University Hospital Bucharest Romania. We statistically analyzed the distribution by age, gender, facial location, the time from onset until the presentation, the type of tumor, the size of the tumor, the margin status, and the recurrence. Results were as follows: median age at 70 years, with an even gender distribution. The most affected areas were the cheek, followed by the nose, forehead, and eyelids. We calculated the dimensions of the tumors between 1.57 mm^2 and 1,846 mm^2, with a median value at 235 mm^2, and a mean value at 421.23 mm^2. Patients in whom safe margins were not obtained had a 4.15 times higher relapse rate versus the ones with safe margins at the first intervention, with a high statistical significance – p=0.002 (15% recurrence rate if safe margins were not obtained, versus 4.1% if margins were safe).

Conclusion. When discussing tumor excisions, one of the most controversial topics is that of safety edges. Currently, even if there are recommendations, a unified protocol is not formulated, which is why we found it useful to research this topic with extensive medical associations.

Keywords: *skin cancer, tumor excision, safety edge*

INTRODUCTION

Tumors represent an important part of the plastic surgeon's practice, surgical excision followed by reconstruction is the most frequently used procedure [1].

The current paper intends to present evidence-based information for such procedures, to establish the current status of cutaneous tumors approach in our clinic, in Romania, compared international guidelines, and to gather a set of recommendations for skin tumors surgery.

MATERIAL AND METHODS

The study is analytical observational and prospective – based on 303 patients who were diagnosed with facial malignant tumors, between 2004 and 2015, in the Plastic and Reconstructive Surgery Clinic, Emergency University Hospital Bucharest Romania.

The inclusion criteria were chronic malignant lesions of the face, with the complete histopathological result, which mentioned the surface and depth, the exclusion criteria

[1] Carol Davila University of Medicine and Pharmacy Bucharest, Romania
[2] Plastic and Reconstructive Surgery Clinic, Emergency University Hospital Bucharest, Romania

were psychiatric disorders, epilepsy, patients who do not cooperate, incomplete histopathological result, tumors that affect other areas that the skin (ENT, ophthalmological, BMF).

Tumor surgical protocol, for malignant tumors, the excision aimed to encompass a safety margin of 3-6 mm. The excised pieces were sent for histopathological examination and the final and complete diagnosis was set after the result was available (7-21 days). The first postoperative evaluation was performed at a median of 3 weeks, and the patients were followed up every 3 months for 2 years.

The collected data was uniformly analyzed; statistical analysis was performed using Microsoft Office Excel for Windows, SPSS version 21.0 (Statistical Program for Social Sciences), and EpiInfo version 7. Non-parametric tests were used, as the studied population did not have a normal distribution. To establish risk rates, we computed the odds ratio (OR) and 95% confidence intervals using EpiInfo. Statistical significance was established for $p < 0.05$. To correctly interpret certain numerical variables and especially how these values may influence the safety margins, as well as the reconstructive procedures, we used ROC curves (receiver operating characteristic) – SPSS 21.0.

RESULTS

In the selected study group the distribution:
- by age was between 35-97 years, with the average age at approximately 71;
- by sex was 50,16% (152) vs 49,84% (151)-male vs female cases.

Analyzing the time since the first detection of the lesion and the moment of presentation to the doctor, we observed an average of 58 months and a median at 24 months; also, 19.3% of the patients had received different treatments for the lesions before presentation in our clinic.

The types of cutaneous malignant tumors were: 215 (70.95%) basal cell carcinomas, 56 (18.48%) squamous cell carcinomas, 5 (1.65%) malignant melanoma, 20 (6.6%) metatypical and mixed carcinomas, non-melanoma tumor relapses 5 cases (1.9%), and 2 cases of metastasis.

Depending on the location related to the face segments, we recorded: 94 lesions (31.03%) on the cheek, 52 lesions (17.16%) on the nose, 47 lesions (15.51%) on the forehead, 35 lesions (11.51%) on the eyelids, 17 lesions (5.61%) on the lip, 17 lesions (5.61%) on the ear, 2 (0.6%) chin lesions, 32 (10.56%) tumors with mixed locations and 7 (2.31%) tumors with an extended location.

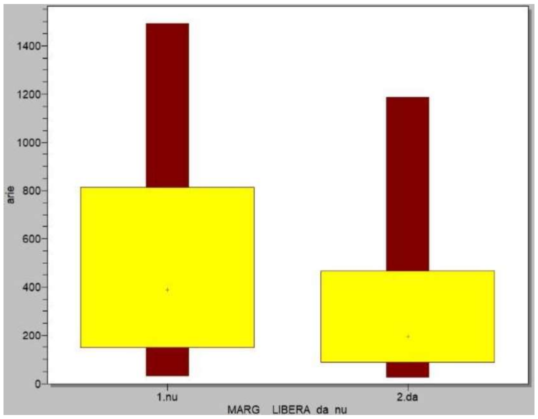
Basal cell carcinomas were most commonly located on the cheek – 32.1%, nose – 18.1%, forehead – 14.9%, eyelids – 14%, ear – 4.7%, lip – 2.8%, and the squamous cell carcinoma were more commonly in cheek – 28%, lips – 22%, nose – 20%, forehead – 18%, eyelid – 6%.

We calculated the dimensions of the tumors between 1.57 mm^2 and 1,846 mm^2, with a median value of 235 mm^2, and a mean value at 421.23 mm^2.

Analyzing the tumor margins, we calculated that the safe margin (tumor-free) was obtained at 75.6% of the patients.

When the dimensions of the tumors were analyzed depending on the safe margin rate, we observed that the patients where safe margins were obtained had a median tumor dimension of 197.82 mm^2, significantly lower than the median dimension in patients where the margins were invaded (405.84 mm^2), p=0.0011 (Figure 1). Similar differences were recorded when comparing median depth of tumoral excisions for safe margins (5 mm), versus invaded margins (6 mm), p>0.05.

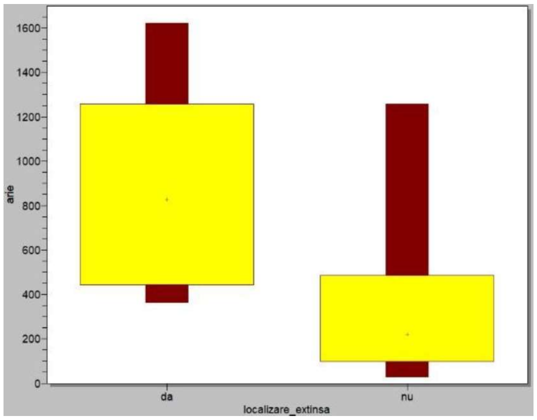
Figure 1: Free margin



The rate of obtaining free margins depending on tumor location was as follows: for lips and chin were completely removed in all cases (100% rate of free margins) eyelid – 71.42%, nose – 73.06%, cheek – 72.33%, forehead – 72.34%, chin – 86.4%, ear – 64.70%, extended location – 57.1%, mixed location – 100%. For tumors with mixed locations, free margins were obtained in all patients (rate 100%), whereas for tumors with a unique location, the rate was 89.4% (p<0.05).

This apparent paradox is related to the lower medium dimensions of tumors with mixed location – approx. 146 mm^2 versus 247 mm^2 (for tumors with strict location), p>0,05. For tumors with extended location, on more than one esthetic unit, usually with a long history of evolution, free margins were obtained in only 62.5% of cases, presenting a 1.9 times higher odds ratio for lack of safe margin versus limited location tumors ($p>0.05$). The median dimensions of these tumors (extended location) was also significantly higher (1,041 mm^2 versus 219 mm^2, $p=0.0007$) for tumors limited to one esthetic unit.

Figure 2: Extensive location



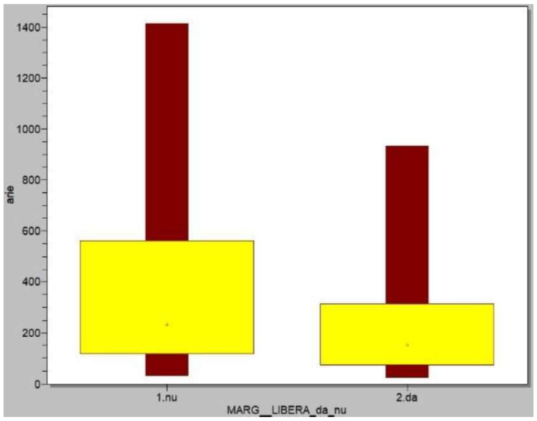
For malignant tumors, free margins were obtained in 64.20% of squamous cell carcinomas, 79.06% of basal cell carcinomas, 100% for melanomas, and 75% for metatypical and mixed carcinomas.

When analyzing the rate of safe margins depending on tumor dimensions for malignant tumors, we observed that the median dimension for basal cell carcinomas with free margins was 152.29 mm^2, versus 235.5 mm^2 for invaded margins, $p=0.017$.

For squamous cell carcinomas, median dimensions for free margins was 447.45 mm^2 compared to 706.50 mm^2 for non-tumor free.

For the most aggressive tumor, malignant melanoma, free margins were obtained for all patients (100% rate), due to the strict surgical protocol in these cases regarding macroscopic safety margins.

Figure 3: Free margin

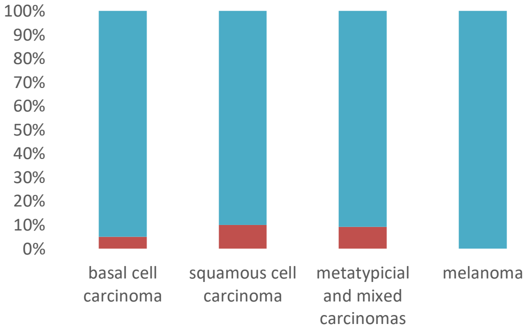


For more rare tumors (metatypical and mixed carcinomas) we obtained free safe margins in tumors with a median dimension of 663.53 mm^2 compared to 710.89 mm^2 for invaded margins.

We analyzed the recurrence rate for patients with malignant tumors and we observed that it appeared in 6.3% of the cases.

The recurrence rates differed on the type of tumor: 5.0% for basal cell carcinoma, 10% for squamous cell carcinomas, 0% for malignant melanomas, and 9.1% for mixed and metatypical carcinomas (Figure 4).

Figure 4: Extensive location (recurrence yes ●, recurrence no ●)



We made a separate analysis of the most frequent malignant tumors, respectively basal cell, and squamous cell carcinomas. Basal cell carcinomas had a very low relapse rate, with a relative risk of 0.48 ($p>0.05$) versus all other malignant tumors. The squamous cell carcinomas had a relapse risk of 1.90 ($p>0.05$) versus other malignant tumors.

Patients in whom safe margins were not obtained had a 4.15 times higher relapse rate versus the ones with safe margins at the first surgery, with a high statistical significance – $p=0.002$ (15% recurrence rate if safe margins were not obtained, versus 4.1% if margins were safe).

We did not observe any significant difference when we analyzed the recurrence rate by tumor dimensions.

Also, although the depth of the recurring tumors was higher than the depth of non-recurring ones (6 mm versus 5 mm), the difference was not statistically significant.

DISCUSSION

Skin tumors are the most common tumors, which is why reconstruction after tumor ablation is the most frequently performed procedure by the plastic surgeon and one of the most active areas of expertise [1]. More than in any other surgical area, the approach for facial tumors has to include a correct and complete tumor resection with a minimum area of excised tissue to preserve the function and shape of the reconstructed area. Our main interest in this study was represented by malignant facial tumors.

In our group, the median age was around 70 years and we observed an almost even gender distribution, consistent with the data reported for basal cell and squamous cell carcinomas [2-5]. Regarding the distribution by aesthetic areas, the most affected ones were the cheek, followed by the nose, forehead, and eyelids.

Regarding malignant tumor pathology, we found that basal cell carcinoma was most frequent, followed by squamous cell carcinoma; metatypical carcinomas – aggressive variants of basal cell carcinoma (they have squamous cell carcinomas behavior). This data overlaps the numerous reports that basal cell and squamous cell carcinomas are most common in the face [6-9, 21].

Analyzing the tumor size, we obtained a median size for the entire group of 303 patients, of 428.53 mm^2. The sizes of the tumors observed in our study are quite high, much larger than those reported by other studies. This was correlated with an increased positive margin rate, which in turn increases the risk of subclinical extension and recurrence [11].

When analyzing separately patients with basal cell carcinomas, we observed that free margin was obtained in 79.06% of cases. A meta-analysis of the literature led by Gulleth et al. on 16,066 cases, encompassing 106 articles on basal cell carcinomas, revealed an average diameter of basal cell carcinomas of 11.7 mm with an average percentage of free margins of 86% ± 12% [12]. Malik et al. in their analysis of 1,832 basal cell carcinoma obtained 86% negative margins excisions [13]. In a study on 2,016 cases for BCC with a diameter smaller than 10 mm, Breuninger obtained a probability of negative margin between 70%-95% depending on the size of the safety margin taken, 2, 3, or 5 mm [14]. In our group, the median dimension for basal cell carcinomas with positive margins was 235.50 mm^2, corresponding to lesions of approximately 23 mm/10 mm. The majority of available data on basal cell carcinomas report small lesions, respectively under 20 mm largest diameter [4, 5], whereas our series comprises patients with much larger lesions, as described above. Therefore, this could explain the lower rate of safe margins in our group, which is related to bigger lesions with a more prolonged evolution.

For squamous cell carcinomas, the median size for excisions with free margins was 447.45 mm^2, versus 706.50 mm^2 for invaded one, with 64.2% of negative margins. Studies on squamous cell carcinomas are much smaller, but we note the results of the prospective study by Peed-Yau Tan et al. in which although the authors do not mention the size of the lesions, they achieved a percentage of only 7.6% excisions with invaded edges [15]. Talbot S. and Hitchcock B. report an invaded edge of 14% in a study on basal cell and squamous cell carcinomas [16]. Again, the tumor size in our patients is quite high, much higher than the limits considered significant (respectively 20 mm largest diameter)[17], thus accounting for the lower rate of free margins.

Another variable tracked in our study was the depth of tumor invasion. There is no clear recommendation in the literature regarding how deep the excision should go; however, for basal cell carcinomas, tumor depth is correlated with the risk of recurrence, and respectively for squamous cell carcinoma, with the rate of metastases [10, 18]. Breuninger reported that, for over 6 mm depth, the metastases rate in squamous cell carcinoma is 15%, and Motley emphasized the depth of 4 mm as associated with recurrence [19]. In practice, deep excision is performed according to what is found intraoperatively and depending on the surgeon's experience. The average excision depth in our free margins lot was 5 mm, while for invaded edges it was 6 mm.

For basal cell carcinomas, recurrence occurred in 5% of patients with negative margins and 10% for positive margins, and for squamous cell carcinoma, respectively in 10% for negative margins and 15% for positive margins. In our study, we found no statistical relevance for recurrence concerning dimensions and tumor depth. In the literature, the BCC recurrence rate varies between 0-10.1% for complete excision, and for incomplete excisions, it is estimated at 27% but can reach as high as 35.5% [12, 20, 21, 23]. For SCC the local recurrence rate varies between 1.7-7% in some studies [24], but it can reach even 53.6% depending on location, the grade of differentiation, perineural involvement, and surgical excision method (standard or Mohs surgery) [25].

The first rule in nonmelanoma skin cancer surgery is to obtain a complete excision with negative margins. In our study, most of the cases had a long evolution period before the presentation, which explains why approximatively 57% were large tumors, above 2 cm. In the cases with positive margins, a re-excision was performed where it was possible, or the patient was referred to the oncology service.

CONCLUSIONS

When discussing tumor excisions, one of the most controversial topics is that of safety edges. What is the size of the safety edges required for complete excision, with free tumor margins, thus ensuring the lowest recurrence rates, and at the same time with a minimal defect for a successful reconstruction?

Currently, even if there are recommendations, a unified protocol is not formulated, which is why we found it useful to research this topic with extensive medical associations.

Factors that influenced infection complications in combat related penetrating brain injuries during conflict in Ukraine

Perekopaiko Yurii[1], Polishchuk Mykola[1], Danchyn Andriy[2], Goncharuk Oksana[1], Danchyn Georgii[2]

Abstract: *Infection complication has a major impact on outcomes of patients with combat related penetrating head injuries. There is still a discussion around which factor influence outcomes and infection complication. In the beginning of war, in 2014, the evacuation system was not ready for a sudden start of hostilities because of limited medical resources, the lack of neuro visualization in the frontline, the lack of trained personnel provided first aid to the wounded.*

Aim: The aim of this study is to determine the factors that influenced the development of infectious complications in penetrating combat head injuries with limited medical capabilities on theatre

Materials and methods: This is retrospective study of 79 military cases with penetrating head injuries, which was received during the fighting in eastern Ukraine in the period from March 2014 to the end of December 2017. Information was collected on demographics, evacuation assistance, type of injury and infectious complications. R commander was used for statistical analysis. Statistical significance was defined as p<0.05.

Results: Infection complication of CNS were detected in 31 cases (39,24%). Factors that influence rate of infection are low GCS on first evaluation (p<0.001), CSF leak (p=0.002), ventricular injury (p<0.005), installation of tidal drainage (p=0.005), superficial wound infection (p=0.013) and wound dehiscence (p<0.001).

Conclusions: There are many controversies in managing penetrating gunshot wounds to the head. Still exist lack of information that neurosurgeon can trust. Data even about small samples still very informative.

Keywords: *infection complications; penetrating brain injury; military trauma; Ukraine*

BACKGROUND

Infection complications (IC) is one of most common reason for unfavorable outcomes after penetrating head trauma [1]. Infection is a reason for severe morbidity and significantly influences mortality rate. This complication prolongs patients' hospitalization time, as well as delays the recovery process with rehabilitation and prevents soldiers return to the battlefield [2]. The rate of IC in combat penetrating trauma higher than in civilian gunshot wounds. Mostly this is due to extended time to the first aid and extreme conditions existing at the war theatre [8]. The war in eastern Ukraine has been going for more than 7 years. In early 2014, the evacuation system was not ready for a sudden rise of hostilities. The most limitations included limited medical resources, the lack of computer tomography (CT) at the frontline, the lack of trained first aid personnel providers.

The purpose of our paper is to determine whether known risk factors for the development of infectious complications had influence to our sample group and what other possible factors could influence outcomes.

MATERIAL AND METHODS

This is a retrospective study of 79 patients with penetrating combat related brain injury. The study based on medical records of patients that were treated at National Military Medical Clinical Centre "Main Military Clinical Hospital" (NATO Role IV) from May 2014 until 31 December 2017. All

patients participated in military conflict in Eastern Ukraine. All injured were evacuated through all echelons. Non-penetrating head injuries were excluded from the analysis.

Information collected from patient recordings include demographics, clinical examination findings during evacuation and in treating hospitals, laboratory results. Computer tomography scans were evaluated by neurosurgeon and radiologist separately. Surgical and therapeutical interventions after injury were noted.

Statistical analysis was performed using R version 3.6.3 (http://www.r-project.org). In univariable analysis, variables were compared between groups by Fisher's exact test for categorical variables and the Wilcoxon signed-rank test for numerical variables. Statistical significance was defined as $p<0.05$. Local ethics committee approval was obtained before the study.

RESULTS

From initial analysis of 109 patients with combat related head injury, 79 had penetrating brain injury. Type of injury included: penetrating (51 cases), perforating (8), ricochet (8), tangential (7), blast related penetrating injuries (5). All wounded were males. Age at presentation was 19.9 to 54.4 years (mean= 31.8, SD=8.4).

Level of consciousness was evaluated with Glasgow Coma Scale (GCS). We divided all patient into three groups according initial GCS. In first group GCS 3-5 were 6 patients, GCS 6-12 – 20 patients, GCS 13-15 – 51 patients, no information was available for two patients. Eight patients deteriorated during evacuation, 28 patients had the same level of consciousness, 32 improved, and in 11 cases information was not available. Loss of consciousness in battlefield for different periods of time was documented in 17 cases.

Bullet gunshot wounds were found in 16 cases, missile fragments injury in 58 cases, and 5 cases had injury related to blast wave impact. Isolated head injury was in 39 cases. Multiple injuries of different parts of the body were detected in 40 cases: 26 cases were combined with extremities, 19 cases with chest, 13 cases with face, 13 cases with abdomen, 13 cases with eyes, 4 cases with neck region. In 28 cases head injury was combined with more than 2 body regions. Injury severity score (ISS) were calculated in each case - average ISS was 26.6 (min 9, max 49, SD=9.1). In case of spine injury all patients evaluated with American Spine Injury Association (ASIA) score: grade A – two, grade D – four, grade E – four.

Head computer tomography performed in all cases (Light Speed VCT 64, General Electric, USA) during admission and when needed – in case of deterioration, appearance of new neurological deficit, routinely after surgery.

Initially retained bone fragments was in 63 patients, removed in 32 cases in previous echelon. Retained metallic fragments was in 58 patients, removed in 27 cases on previous stages. On last CT before discharge from hospital bone fragments detected in 26 cases, metallic in 28.

Patients operated because of epidural hematoma (EDH) in 11 cases (five combined with subdural hematoma (SDH), SDH was in 17 cases, intraventricular haemorrhage was in 13 cases, ventricular system weas injured in 17 cases.

Bullet or missile entrance wound was in 31 cases in frontal region, parietal in 22, temporal region in 13 cases, occipital in three, face in one, basal in one, transorbital in three cases. Exit wound was in frontal region in three cases, temporal in three, parietal in one, occipital in one case.

Paranasal air sinuses were injured in 23 cases: frontal sinus in 17 cases (two cases combined with maxillary), basal sinus in two cases (one with maxillary), one case maxillary, in three cases were injured mastoid air cells.

Infection complication of central nervous system (CNS) were detected in 31 cases (39.24%) – details in Table 1.

Table 1: Types of infection complications

Nosology	Number
Meningitis	17
Meningoencephalitis	6
Abscess	4†
Ventriculitis	2*
Empyema	2

*† one combined with empyema, two with ventriculitis, two with meningoencephalitis; * one combined with meningoencephalitis*

Infection complications were proved by clinical and laboratory data. Records of physical examination and local wounds status were also collected. Cerebrospinal fluid (CSF) cultures was analyzed in 12 cases. P. aeruginosa was found in three cases, S. cohnii was revealed in one case. Wound culture was performed in four cases, in one case grew S. aureus.

In 24 cases performed 24 reoperations: 17 patients underwent two surgeries, three patients underwent three surgeries, in one case four reoperations, in three cases five reoperations. Reasons for reoperations varied: CSF leak, removal of retained bone and metallic fragment, infection complications with mass effect, CSF diversion procedures.

Table 2 shows factors that influence rate of infection complications after combat related penetrating brain injury.

Outcomes at discharge was evaluated with Glasgow Outcome Scale (GOS) and present in Table 3. Six cases with GOS1 have different types of infection complications.

DISCUSSIONS

Infection complication after penetrating combat related trauma one of the main factors that influence mortality and morbidity rate [1-3,6,13]. It can prolong staying in hospital and demand significant financial and physical resources, prolong rehabilitation process [1]. In our series infection complication was detected in 39.24% (31 cases), that is typical for centre which collect patients from previous levels [7], but this is significantly higher than in recently conflicts (from 5.2 to 31%) [1,7,8,10,11,14]. Structure of infection complications also changed – in pre – and early antibiotic era mainly were diagnosed abscesses and subdural empyema [15], now its meningitis and encephalitis [2,3,5-7].

Our results along with data from other studies showed several factors that influence rate of infection complications after combat injuries – low CGS on admission [1,13], CSF leak [1-4,11,12], ventricular injury [3,4,16] and wound dehiscence [6,13].

Retained bone fragment and repeated surgeries has some tendency to be influence factor but did not reach significance level (p=0.086, p=0.099 accordingly). These factors also described in literature as possible reasons for infection complication with additional circumstances for example CSF leak [5]. There are two different strategies for management retained bone fragments. First strategy includes an aggressive and complete removal of all retained fragment [3,6,7,9,10]. Second is so called «less aggressive» strategy that was proposed after Israeli Lebanese conflict. Authors maintain that less aggressive tactic in removal of fragments are better for outcomes without major influence on infection rate [1,4,6,8-11].

We didn’t detect in our study that injury through air sinuses can cause higher rate of intracranial infection complications (p=0.62) but some authors describe it as a factor that influence [3]

Also type of penetrating agent, ISS on admission didn’t influence rate of infection complication in our study, but other papers show opposite data [2,16].

Some authors believe that soldiers which were injured in the beginning of conflict have more chances to have an infection [12]. In our study we also can follow similar tendency of this but it did not reach a significance level (p=0.063). This can be explained by lack of organized an evacuation system at the beginning of the war when time of evacuation was extended sometimes up to 3 days.

Information regarding usage of tidal drainage difficult to find in modern literature. It was widely used during the Second World War by the Soviet Army [15,17], and still used in the so-called post-Soviet countries [2,18]. This method of drainage is not commonly used in our hospital. In our series, 12 out of 31 patients, who had IC, had such drainage during evacuation. Our hospital does not support such widespread usage of tidal drain, and in our opinion, this technique should be minimized as it is a predictor of infectious complications ($p<0.005$).

Time to surgery was hard to evaluate in our study. We can only divide surgery in two major groups – surgery that done in firs 24 hour and later. We cannot detect major difference between this groups. But some authors showed that patients which were operated in first 24 hours have better neurological outcomes and less IC [14,16].

CONCLUSIONS

We found factors associated with infectious complications that were earlier described in literature and also working in our sample as CSF leak, GCS on admission, injury reaching ventricular system, local wound infection and dehiscence. There are many controversies about retained fragments and their role in cause IC. Fast qualified medical care is likely to reduce the risk of IC. It is important to transform a gunshot wound from a penetrating to a closed non-penetrating one, which is the prevention of cerebrospinal fluid and IC. In the case of contaminated wounds, the possibility of installing tidal drainage should be avoided, as this increases the risk of infection.

Limitations

Our study has several limitations. Firstly, some of the data were missing due to its retrospective design, all date were collected from paper histories and sometimes not all hand written information can be right identified and probably missed. In addition, the relatively small sample group prevent us to analyze the contribution to infection risk of other important factors.

Fever of unknown origin

Gina Gheorghe[1,2], Gabriela Ceobanu[1], Florentina Gheorghe[3], Ovidiu G. Bratu[1,4], Nicolae Bacalbasa[1,5], Simona Bungau[6], Camelia C. Diaconu[1,2]

Abstract: *Fever of unknown origin (FUO) is a diagnosis that describes a prolonged febrile illness without an established cause, despite investigations. From the first definition of the medical condition (given by Petersdorf and Beeson in 1961) the diagnostic criteria have changed over time, intending to improve the management and outcome of these patients. The main causes of FUO fall into 4 categories: infectious, non-infectious (inflammatory), neoplastic and diverse causes. The etiology of FUO has changed over time, due to ever-changing disease patterns and the development of diagnostic techniques. A significant percentage of patients with FUO remain without an etiologic diagnosis, despite advanced diagnostic tests. Gathering potentially diagnostic clues through history, physical examination and nonspecific key paraclinical abnormalities is the basis for the diagnosis of FUO.*

Keywords: *fever of unknown origin, infections, malignancies, systemic inflammatory diseases*

INTRODUCTION

Fever of unknown origin (FUO) was first defined in 1961 by Petersdorf and Beeson as a medical condition that has the following three characteristics [1]:

- Body temperature 38.3° C (101° F) at three or more successive measurements.
- A duration of at least 3 weeks.
- Uncertain diagnosis after one week of hospitalization.

In the following years, the definition of FUO changed. Immunosuppressed patients were excluded from this category because they have etiological peculiarities and require a different therapeutic approach. Thus, the current definition of FUO includes the following diagnostic criteria:

- a body temperature ≥38.3°C (101°F) at least 2 determinations;
- the duration of illness for ≥ 3 weeks or recurrent febrile episodes for ≥ 3 weeks;
- the absence of immunosuppression, defined as HIV infection or known hypogammaglobulinemia, treatment with prednisone 10 mg or equivalent for a duration ≥ 2 weeks in the previous 3 months before the onset of fever, and neutropenia for a period ≥1 week 3 months before the onset of fever;
- uncertain diagnosis, despite a rigorous case history and clinical examination and the following laboratory investigations: complete blood count, erythrocyte sedimentation rate, ferritin, three blood cultures, tuberculin skin test, C-reactive protein, electrolytes, total proteins,

EPIDEMIOLOGY

Scientific and technological progress in the microbial diagnosis and classification of the pathogenesis of rheumatic diseases have led to a higher rate of etiological diagnosis among patients with fever. Thus, if in 1930, 75% of patients with fever had no identified causes, nowadays-true FUOs are uncommon [4, 5]. The causes of FUO vary greatly with age. Among children, the most common are viral infections, while among adults' multisystem diseases, such as rheumatic diseases or sarcoidosis, are more likely [5, 6]. Furthermore, geographical region and economic development have an important influence on the etiology of this disease. Thus, in developing countries, the most common causes of FUO are tuberculosis, typhoid fever, amebic liver abscesses and acquired immunodeficiency syndrome (AIDS). In developed countries, the travel of inhabitants to certain areas is a risk factor, resulting in the identification of rare diseases, such as malaria, filariasis, schistosomiasis, Q fever, relapsing fever, Zika virus, fever leash, etc. [5, 7]. Travelers may be infected with microorganisms to which local residents are not vulnerable, because of pre-existing immunity. The diseases contracted while abroad may have a very high incubation period, symptoms (such as fever) occurring after a period from the moment of return. This reduces the chance of an etiological diagnosis [5, 8].

A special category of patients is immunosuppressed patients, such as those with AIDS or known neutropenia. In the case of AIDS, the causes for fever are infections (79%) and malignancies (8%). In 9% of cases, the cause cannot be identified. Regarding the infectious agents, more than half of the cases were due to mycobacteria, especially atypical, the most common being the mycobacterium avium complex (MAC). Regarding malignancies among HIV-infected patients, lymphomas, particularly non-Hodgkin's lymphomas dominate [5]. Febrile episodes associated with neutropenia are most frequently caused by bacteremia, followed by the underlying disease, which has resulted in neutropenia, certain drugs, blood products, and in the case of transplanted patients, allograft rejection [5].

Usually, fever improves with an increase in neutrophils. When fever persists, although the neutrophil count has normalized, the diagnosis of hepato-splenic candidiasis can be considered [9].

ETIOLOGY

The etiology of FUO has changed over time, due to ever-changing disease patterns and the development of diagnostic techniques. The main causes of FUO fall into four categories: infectious, non-infectious (inflammatory), neoplastic and diverse causes [10]. There is also a significant percentage of cases when the etiology of fever remains unknown. A prospective multicenter study estimated the percentage of patients with FUO of 51% [11]. Over time, the frequency of malignancies and infectious diseases as causes of FUO has decreased in favor of noninfectious inflammatory diseases and cases without an etiological diagnosis [12]. From infectious diseases, the most common causes of FUO are tuberculosis and abscesses [13]. The most common malignancies presenting with fever are lymphoma, especially non-Hodgkin, leukemia, renal cell carcinoma, hepatocellular carcinoma, and liver metastasis [13]. Common noninfectious febrile inflammatory conditions correlate with patients' age. Thus, in young patients, systemic juvenile idiopathic arthritis and giant cell arteritis are frequent causes of fever [13]; in older patients, connective tissue diseases or granulomatous diseases are more frequently encountered. Table 1 presents the most common causes of FUO [10, 13, 14].

DIAGNOSIS

FUO remains a diagnostic challenge, considering that there are over 200 disorders that enter in the differential diagnosis. The diagnostic approach therefore should focus on a thorough history of the patient and finding hallmark clinical features that are characteristic of each disease, along with selective non-specific laboratory tests [13]. A detailed history of the patient can provide important diagnostic clues for FUO and should aim to orientate the paraclinical investigations necessary for the positive diagnosis [15]; it should include the history of present illness, data about recent travel, past medical history, drug history, social history and family history (Table 2) [16].

Every FUO category has clinical hallmarks the clinician should search during physical examination [15-18]. Searching potentially diagnostic clues (PDC) during the clinical exam is an important step in the diagnostic workup. PDCs are defined as "all localizing signs, symptoms, and abnormalities potentially pointing toward a diagnosis"[19]:

1. Infectious diseases:
- Spinal tenderness points: suggest spinal tuberculosis, subacute vertebral osteomyelitis;
- Hepatomegaly: Q fever, typhoid/enteric fever, rat bite fever, brucellosis;

- Splenomegaly: miliary tuberculosis, Epstein-Barr virus (EBV) infection, cytomegalovirus (CMV) infection, typhoid/ enteric fever, subacute bacterial endocarditis, Q fever;
- Regional adenopathy: characteristic of cat-scratch disease;
- Epididymo-orchitis/epididymal nodule: EBV infection, renal tuberculosis, brucellosis;
- Cutaneous findings of endocarditis: Osler nodes, Janeway lesions, splinter hemorrhages;
- Heart murmurs: suggest bacterial endocarditis.

Table 1: The most common causes of FUO.

Infections	Malignancies	Systemic inflammatory diseases	Miscellaneous
• Bacterial (tuberculosis, occult abscess, complicated urinary tract infection, osteomyelitis, Q fever, rickettsia infections, enteric fever, brucellosis) • Viral (Epstein-Barr virus, cytomegalovirus, human immuno-deficiency virus) • Parasitic (malaria, toxoplasmosis) • Fungal (histoplasmosis)	• Hepatocellular carcinoma (or liver metastasis) • Leukaemia • Lymphoma, especially non-Hodgkin's • Myelodysplastic syndromes • Multiple myeloma • Renal cell carcinoma • Sarcoma • Colon cancer • Lung cancer • Atrial myxoma	• Giant cell arteritis • Polyarteritis nodosa • Adult Still's disease • Takayasu's arteritis • Granulomatosis with polyangiitis • Mixed cryoglobulinemia • Systemic lupus erythematous • Sarcoidosis • Granulomatous hepatitis • Antiphospholipid syndrome • Behçet's disease	• Drugs (e.g. sulfone-amides, penicillin, nitrofurantoin, vancomycin, antimalarials, H1- and H2-blocking antihistamines, barbiturates, phenytoin, nonsteroidal anti-inflammatory drugs, hydralazine, methyldopa, quinidine, procainamide, anti-thyroid drugs, etc.) • Environmental (metal and polymer fume fevers) • Factitious fever • Disordered heat homeostasis • Alcoholic hepatitis • Venous thrombosis and thromboembolism • Hematoma • Hyperthyroidism and subacute thyroiditis • Pheochromocytoma • Adrenal insufficiency • Familial Mediterranean fever • Tumour necrosis factor receptor-1–associated periodic syndrome (TRAPS) • Hyper-IgD syndrome • Muckle-Wells syndrome • Familial cold autoinflammatory syndrome

2. Malignant diseases:
- Cachexia;
- Diffusely enlarged lymph nodes: lymphoma;
- Erythema nodosum: lymphoma;
- Sternal tenderness points: bone marrow disorders: preleukemia, myeloproliferative disorders;
- Eye examination: Roth spots - lymphoma, atrial myxoma; cytoid bodies - atrial myxoma; retinal hemorrhages - preleukemia.

3. Systemic inflammatory disorders:
- Skin rash: may suggest systemic lupus erythematosus (SLE), adult Still's disease [14];
- Unequal pulse: Takayasu's arteritis;
- Lacrimal gland enlargement: late-onset rheumatoid arthritis (RA), sarcoidosis, SLE;
- Oral ulcers: Behçet's disease, SLE;
- Lymphadenopathy: SLE, sarcoidosis;
- Heart murmur with negative blood cultures suggests a possible diagnosis of Libman-Sacks endocarditis.

4. Miscellaneous diseases. Miscellaneous fevers of unknown origin are often diagnosed based on historical clues rather than clinical findings. Relative bradycardia may suggest drug fever. Cirrhosis is often overlooked as a possible cause of FUO [15, 16]. Splenomegaly may be another important clue that may suggest regional enteritis, cirrhosis or hyper-IgD syndrome.

Paraclinical investigations

Before initiation of any diagnostic tests, treatments, such as antibiotics or glucocorticoids, must be stopped, as they can mask different signs and symptoms and thus delay the diagnostic process.

In any patient with FUO, the following basic laboratory tests are necessary: erythrocyte sedimentation rate (ESR) or C-reactive protein (CRP), hemoglobin, platelet count, leukocyte count and differential, electrolytes, creatinine, total protein, serum protein electrophoresis, alkaline phosphatase, aminotransferases (AST, ALT), LDH, creatine kinase, antinuclear antibodies, rheumatoid factor, urinalysis, together with blood cultures, urine culture, a tuberculin skin test or Interferon-Gamma Release Assays (IGRA), and imaging studies - chest X-ray, abdominal ultrasonography [19].

Table 2: Key clues to FUO derived from history.

Infectious Diseases	Malignant disorders	Systemic inflammatory diseases	Miscellaneous Disorders
Prior/invasive procedures or surgeries (abscess)	Significant weight loss (2 lbs/week)	Arthralgias	Fever periodicity (cyclic neutropenia)
Dentition (apical abscesses, subacute bacterial endocarditis)	Anorexia	Myalgias	History of lymphadenopathy (Rosai-Dorfman, Kikuchi's disease)
Antecedent/concomitant infections	Post-hot bath pruritus	Dry cough (Giant cell arteritis)	Neck/jaw pain (subacute thyroiditis)
Animal/pet contact (Q fever, brucellosis, toxoplasmosis etc.)	History of adenopathy	Visual disturbances (Giant cell arteritis)	Inflammatory bowel disease (regional enteritis)
Mosquito/tick exposure (malaria, babesiosis)	History of malignancy	Acalculous cholecystitis (SLE, peri-arteritis nodosa)	Alcoholism (cirrhosis)
Rodent exposure (leptospirosis, rat bite fever)	Pel-Ebstein fever-week long high fevers with week-long remissions (Hodgkin disease)	Family history of systemic inflammatory diseases	Medications (drug fever)
Blood transfusions (CMV, HIV)	-	Jaw claudication (Giant cell arteritis)	Prolonged immobility, car trips, flights (thromboembolic disease)
Immuno-suppressive drugs	-	-	-
Nocturia (prostatitis)	-	-	-
High-risk sexual practices	-	-	-
Travel to an endemic area	-	-	-

Complete blood count contains often-overlooked clues, for example, leukopenia, monocytosis, lymphocytosis-relative lymphopenia, eosinophilia, basophilia, atypical/abnormal lymphocytes, thrombocytosis, and thrombocytopenia. In FUO, an isolated alkaline phosphatase elevation may be a clue for lymphoma [20, 21, 22]. Eosinophilia may suggest polyarteritis nodosa, drug fever, or visceral leishmaniasis. Low levels of hemoglobin or hematocrit may point toward occult hemorrhage or hematoma (often retroperitoneal).

After all potentially diagnostic clues retrieved from the patient's history, clinical examination and paraclinical investigations have been identified, the clinician should make a list of the most probable diagnoses; further specific investigations should be guided by these diagnoses.

If the diagnosis remains elusive, more advanced paraclinical investigations may be necessary. In patients with hepatomegaly or splenomegaly, abdominal computed tomography (CT) scan may be useful in detecting abnormalities such as adenopathy, abscesses or masses [23]. Echocardiography is important in case of suspicion of endocarditis or atrial myxoma. Positron emission tomography-computed tomography (PET-CT) scans help detect obscure infectious/neoplastic causes of FUO, for example, lymphomas, Q fever endocarditis or aortic graft infection [24]. Magnetic resonance imaging (MRI) may be useful in case of osteomyelitis. Digestive endoscopy may become necessary in case of suspicion of inflammatory bowel disease or sarcoidosis [25].

Invasive tests, such as lymph node biopsy, bone marrow biopsy, epididymal nodule biopsy, liver or ileal biopsy may have a high diagnostic yield [26-29]. However, these tests should be ordered based on narrowed diagnostic possibilities [30, 31].

TREATMENT

Treatment should be directed toward the underlying cause once a diagnosis is made. Because they may mask, delay or obscure the clinical manifestations, empirical therapeutic trials with antibiotics [32, 33], glucocorticoids, or antituberculous agents should be avoided in FUO, except in immunocompromised, neutropenic patients, in case of severe systemic illness or those with a rapid deterioration (patients with central nervous system or miliary tuberculosis or giant cell arteritis) [34, 35].

CONCLUSION

FUO remains one of the most difficult diagnostic challenges, as the differential diagnosis consists of over 200 malignant/ neoplastic, infectious, rheumatic/inflammatory, and miscellaneous disorders. It is essential for the clinician to obtain potentially diagnostic clues through a detailed history of the patient, complete physical examination and guided paraclinical investigations. Interdisciplinary consultations may be appropriate in a majority of patients with FUO.

ORIGINAL ARTICLE

Frequency and genotyping of human papillomavirus in patients with DNA tracking technique during 1996-99

Bahareh Panahi[1], Abbas A. Sepahi[1], Mahdieh Farzanehpour[2]

Abstract: *The prevalence of human papillomavirus (HPV) infections and their role in cervical cancer have been well documented in numerous articles, but it seems that a study in this field in developing countries and the Middle East, including Iran. It's not done. Therefore, the present study was designed and performed to investigate the frequency and genotyping of human papillomavirus in patients by DNA tracking technique. This study was a population-based study in which the frequency and genotyping of human papillomavirus in patients by tracking technique was designed and performed on 534 men and women living in Tehran by DNA tracking technique. Sequences obtained using the NCBI site were analyzed at (http://www.ncbi.nlm.nih.gov/BLAST/LaserGene) and Bio edit software. So that in three low-risk groups including 6 and 11 genotypes, Intermediate risk includes 26-31-33-35-39-40-42-45-49-51-52-53 genotypes -55-56-58-59-66-63-83 and High risk includes 16 & 18 genotypes were divided. According to the results, the prevalence of the papilloma virus in the study population was 21.16%, of which 19.46% were in the high-risk group, 69.89% were in the intermediate-risk group and 50.43% were in the low-risk group. According to the results of the present study, although the prevalence of HPV in the study population is less than in many countries in the world, it is suggested that conducting epidemiological studies in the country to extract the true prevalence and plan to prevent and control this disease.*

Keywords: *human papillomavirus, frequency, genotype, DNA tracking technique*

INTRODUCTION

Cervical cancer is the fourth most common malignancy and a major cause of death in women worldwide. Numerous reports show an association between a group of DNA oncogenic viruses and the development of malignancies in the human population, including human papillomavirus [1].

More than 200 different types of human papillomavirus have been found, of which about 40 are capable of infecting the genital tract. Human papillomavirus is classified into two low-risk and high-risk groups based on the degree of malignancy and cancer [2].

In the latest classification published by the World Health Organization, the International Agency for Research on Cancer, genotypes 16, 18, 31, 35, 39, 45, 51, 52, 56, 58, and 59 as high-risk types, other cultivars including genotype 26, 30, 34, 53, 66, 67, 68, 69, 70, 73, 82, 85 and 97 are also known to be carcinogenic types and genotypes 6 and 11, which are known to cause benign lesions of the genital tract. Introduced as low risk types [3].

The progression of cancer requires the expression of viral genes, the entry of viral DNA into host chromosomes, and changes in the genes and gene products of the host cell. This group of viruses requires the DNA polymerase of host cells to replicate the genome, and from the entry points created through fine scratches in the stratum corneum cell layers to reach the basal layer of the epithelium, the location of basal cells and pre-cells. They use instruments that can be reproduced [4]. The E6 and E7 oncoproteins in HPV are key players in carcinogenesis and target tumor-suppressing proteins in host cells. In high-risk HPVs, the E6 protein forms a complex with a ubiquitin ligase [5]. This complex binds to p53, which is followed by the breakdown of p53, which inactivates it. P53 acts as a transcription factor and induces

the expression of genes involved in cell cycle arrest and apoptosis. When E6 is not inactive, the p53 protein increases, causing p53-dependent apoptosis and killing the infected cell before the virus multiplies [6]. E7 protein also exerts its oncogenic effect by inactivating retinoblastoma protein and two proteins related to retinoblastoma protein, p106 and p130 [7].

Retinoblastoma protein suppresses tumors and plays a key role in regulating the eukaryotic cell cycle. In the case of high-risk HPV infection, the E7 protein breaks down the E2F-Rb complex, releasing E2F, resulting in the cell entering the S phase outside the original time, which disrupts the cell cycle [8].

The human papillomavirus completes its evolution as it crosses the basal layer with the superficial cell layers, which increases the expression of the virus's L1 and L2 proteins, which play an important role in their identification. High-risk types of HPV cause lesions in the cervical epithelium, the severity of which varies depending on the extent to which squamous epithelial cells have been replaced by basaloid cells in infected species [9].

Grading CIN III, CIN II, CIN I High-risk HPV is a necessary and insufficient factor in the development of cervical cancer, so other factors associated with cervical cancer include smoking, age, nutrition, race, geographical location, having Multiple sexual partners noted long-term use of birth control pills, weakened immune systems, and host-related factors [10].

The global prevalence of HPV infections in 2012 is estimated at 440 million. In 2012 alone, these infections led to 550,000 cases of cervical cancer and approximately 288,000 deaths [11]. Also, according to published statistics on the diagnosis of human papillomavirus in various diseases, infection of this virus in 99% of cervical cancers, 97% of anal cancers, 70% of vaginal cancers, 47% of penile cancers, 40% of gastrointestinal cancers, 47 The percentage of urological cancer and 11% of cases of oral cancer have been observed [12].

In most of the results obtained from the studies of researchers inside and outside the country, the abundance of 6, 11, 16, and 18 is more than other genotypes. Therefore, the frequency and determination of HPV genotype due to the identification of low-risk and high-risk types have diagnostic and therapeutic value and can be prevented by screening and timely diagnosis of lesions that lead to malignancy. Therefore, it is recommended that women between the ages of 30 and 65 have a screening test every 5 years [13].

Human papillomavirus is known to be one of the most important causes of cervical cancer [14]. HPV infection is a sexually transmitted disease that the prevalence and type of virus that causes it varies depending on the area where people live. Studies in different human populations show that more than 50% of women become infected with at least one type of virus during their lifetime.

Human papillomavirus is a small, uncoated virus with double-stranded DNA of at least 200 different types. About 35 to 40 types of this virus infect the skin epithelium or mucous membranes in the female reproductive system [15]. Most viral infections do not cause specific symptoms or diseases and heal on their own. If the infection persists, the variety of lesions of the virus is high, ranging from benign skin warts that are self-limiting and often appear on the hands and feet to malignant and invasive lesions manifesting as fatal cervical cancer [16].

Condyloma acuminata is one of the most common sexually transmitted diseases. Mucosal types can be divided into high-risk and low-risk according to the risk of disease. High-risk types of human papillomavirus play a major role in causing cervical cancer. Among these viruses, at least 15 types of high-risk viruses cause more than 95% of cervical cancers and 80% of vaginal cancers [17]. Therefore, its accurate diagnosis will have a significant impact on the control and management of this cancer and the promotion of women's health in society.

Currently, 170 HPV genotypes are classified according to the type of biological wall and oncogenicity and their type of racial evolution, types 16, 18, 31, 33, 35, 39, 45, 51, 52, 56, 58, 59, 68, 73, and 82 are known to be high-risk, and types 26, 53, and 66 may also be oncogenic [18]. Abnormal cervical epithelial cells can be detected by Pap smear staining and microscopic observation. However, this diagnostic method is only used for women at risk for advanced disease, and about 50% of the lesions will not be detected if only a Pap smear is performed on them, as the HPV virus does not grow in culture and serological tests are of limited accuracy.

HPV infection triggers a humoral immune response against the capsid protein, which is an antibody that stays in the body for many years (serological tests are not suitable for diagnosing present and past infections [19]. As a result, accurate diagnosis of HPV infection relies heavily on molecular methods.

Molecular techniques can be used to accurately diagnose and identify HPV, as well as to inform the patient and follow up after treatment. Accurate HPV genotyping is essential to classify patients into high-risk or low-risk groups.

Evidence also suggests that the presence of multiple HPV types may reflect repeated exposure to the virus and may be associated with an increased risk of disease progression [20].

Prevalence and genotyping of human papillomavirus in precancerous and cancerous samples with DNA tracking technique from 1396 to 1399 in Tehran to evaluate the health of the female community.

This study aimed to investigate the frequency and genotyping of human papillomavirus in precancerous and cancerous samples by DNA tracking technique.

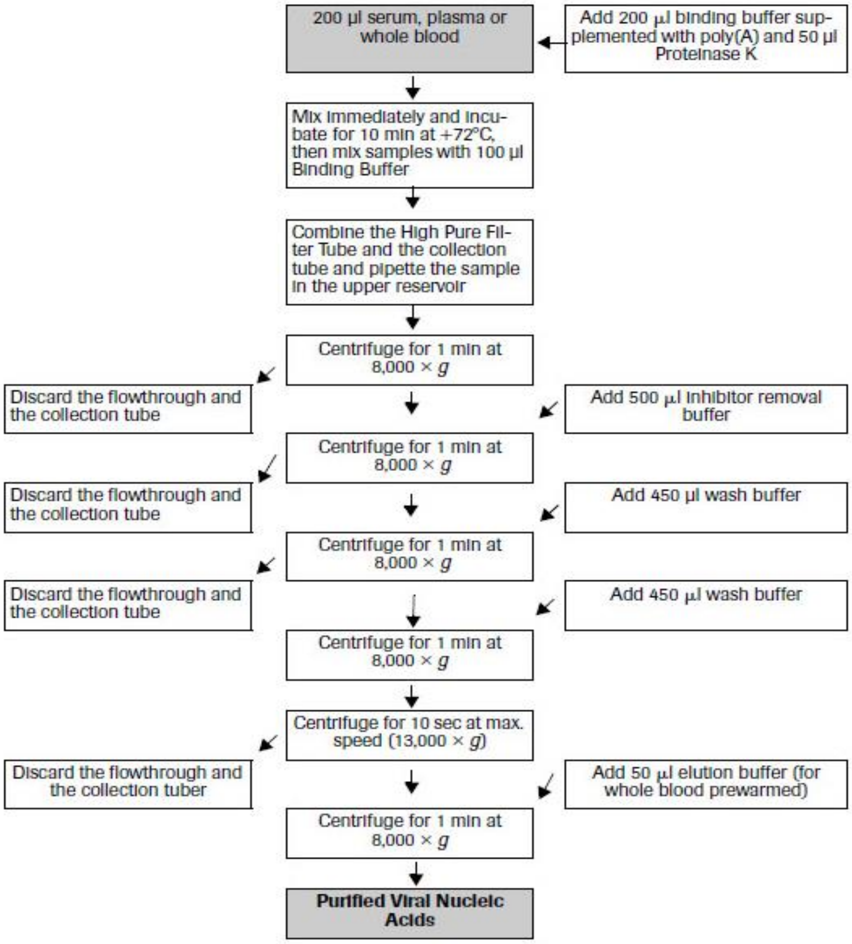
METHODS

This case-control study was performed by collecting 534 biopsy specimens from men and women. All biopsy specimens were examined for the presence of the human papillomavirus genome.

DNA extraction

DNA extraction was performed according to the protocol of a High pure viral nucleic acid kit from Roche (Germany). The steps are summarized in Figure 1.

Figure 1: General process of DNA extraction protocol by High pure viral nucleic acid kit



200 µl serum, plasma or whole blood
Add 200 µl binding buffer supplemented with poly(A) and 50 µl Proteinase K
Mix immediately and incubate for 10 min at +72°C, then mix samples with 100 µl Binding Buffer
Combine the High Pure Filter Tube and the collection tube and pipette the sample in the upper reservoir
Centrifuge for 1 min at 8,000 × g
Discard the flowthrough and the collection tube
Add 500 µl inhibitor removal buffer
Centrifuge for 1 min at 8,000 × g
Discard the flowthrough and the collection tube
Add 450 µl wash buffer
Centrifuge for 1 min at 8,000 × g
Discard the flowthrough and the collection tube
Add 450 µl wash buffer
Centrifuge for 1 min at 8,000 × g
Centrifuge for 10 sec at max. speed (13,000 × g)
Discard the flowthrough and the collection tuber
Add 50 µl elution buffer (for whole blood prewarmed)
Centrifuge for 1 min at 8,000 × g
Purified Viral Nucleic Acids

Quality control of extracted DNA

At this stage, using the PCR technique and targeting the β-Globin gene as a housekeeping gene, quality control was performed, so that samples that were positive for the β-globin gene were considered suitable samples for testing in later stages. Were taken. Samples that were negative for this gene were retested, and if we did not respond again, we would have to retrieve the patient sample.

Table 1: β-Globin gene primers

Pco3	Forward	5′-ACACAACTGTGTTCACTAGC-3′
Pco4	Reverse	5′-CAACTTCATCCACGTTCACC-3′

Nested PCR for human papillomavirus genome

Nested PCR is a modified model of PCR that reduces nonspecific connections in the reaction product (due to propagation of components that are not expected). In this method, two pairs of primers are used to increase the sensitivity of PCR. First, with a pair of first primers over 15-30 cycles, specific pieces of target DNA are amplified. The resulting PCR product is then transferred to another tube and used as a template, and the second stage of PCR is performed by a pair of second primers. In the Nested PCR test to detect HPV, we first used the pairs of primers mentioned in Tables 2 and 3.

Table 2: Sequence of MY09/11 primers (Outer Primers)

MY09	Forward	5'-CGTCC(A/C)A(A/G)(A/G)GGA(A/T)ACTGATC-3'
MY11	Reverse	5'-GC(A/C)CAGGG(A/T)CTATAA(C/T)AATGG-3'

Table 3: Sequence of GP5+/6+ primers (Inner Primers)

GP5+	Forward	5'-TTTGTTACTGTGGTAGATACTAC-3'

The PCR product with MY09/11 and GP5+/6+ primers are 450 and 150 bp, respectively.

Sequencing

To determine the genotype of HPV positive samples, Biosystems ABI 911 automatic device was used using the cyclic sequencing method.

For this purpose, 4 separate PCR reactions are performed, each containing a similar primer and a different ddNTP terminator labeled with fluorescence dye.

Genetic analysis of HPV sequences

Sequences obtained using the NCBI site were analyzed at (http://www.ncbi.nlm.nih.gov/BLAST/LaserGene) and Bioedit software. So that in three low-risk groups including 6 and 11 genotypes, Intermediate risk includes 26-31-33-35-39-40-42-45-49-51-52-53 genotypes -55-56-58-59-66-63-83 and High risk includes 16 & 18 genotypes were divided.

RESULTS

The data obtained from 534 participants in the study were analyzed using descriptive statistical methods (mean, standard deviation, frequency, and percentage) and the results were obtained according to the objectives and hypotheses of this study, respectively.

Table 4 shows the age distribution of the research community in terms of quantitative variables.

The minimum age for men is 24 and the maximum age is 65, the minimum age for women is 19 and the maximum age for women is 75.

The mean and standard deviation of the age of men and women are equal to (35.12 ±77.44), (43.11 ±23.15).

Table 4: Descriptive statistics of quantitative variables

Variables	At least	Maximum	Mean	Standard deviation
Age of men	24	65	35.77	12.44
Age of women	19	75	43.23	11.15

Table 5 shows the PCR findings based on positive and negative criteria. Of the 18 men referred, 3 were negative for papillomavirus, and 15 were positive. Out of 516 female patients, 418 were negative for papillomavirus, and 98 were positive.

According to the results, the prevalence of the papilloma virus in the study population was 21.16%.

Table 5: Report of PCR findings based on positive and negative criteria

Variables	Positive number	Negative number	Percent
Age of men	15	3	13.27
Age of women	98	418	86.72

According to Table 6, 3 men were simultaneously High risk, Intermediate risk, and Low risk, 8 were only Intermediate risk, 3 were Intermediate risk and Low risk and 3 were Low risks.

According to Table 7, 34 women were Low risk, 36 were Intermediate risk, 7 were Intermediate risk and Low risk, 15 were High risk, 3 were High risk and Low risk, and 3 were High risk and Intermediate risk.

DISCUSSION

Today, cancer is a dangerous and deadly disease that is one of the most important causes of death worldwide. In 2012, 14.1 million new cases of the disease were reported worldwide, and the disease has killed 8.2 million people [21]. While the mortality rate and cancer incidence in 2008 was 7.6 million and 12.7 million people, respectively [22]. Approximately 47% of new cancers and 55% of deaths from them occur in developing and less developed countries.

In Iran, cancer is the third leading cause of death and more than 30,000 people die of cancer every year [23]. With the increase in life expectancy and the percentage of aging in the country's population, the advancement of medical science and technology, and the departure of lifestyles from a clean environment free of industrial carcinogens, cancer incidence is expected to double in the next two decades. According to the World Health Organization, the incidence of cancer in Iran in 1399 will reach about 86,000 cases in the total population and the resulting mortality rate will reach about 63,000 cases [24].

Various factors involved in cancer include lifestyle, heredity, environment, host factors, and infectious agents. Infectious agents are one of the most important controllable factors in cancer. Studies show that 17.8% of cancers are associated with infectious agents, among which viral agents are of great importance because about 12.1% of cancers are associated with viral agents [25]. Annually, 1.3 million new cases of cancer are attributed to viruses, and cancers caused by viral agents lead to the death of 1 million people each year [26].

One of the viral families associated with cancer is viruses belonging to the papilloma viridae family. Cervical cancer is the fourth most common cancer in women worldwide [27] and has received much attention today due to the large social and economic costs imposed on society and the health system. Given that cervical cancer has a long and slow progression, early detection, especially in precancerous stages, can help reduce mortality from this important cancer. Current methods for screening, diagnosis, and follow-up of this disease are based on cytological and histological methods; for example, Pap smear, which has been used for many years and is unchanged [28].

Due to the limitations of these methods, including insufficient sensitivity in a study and the need for repeated studies, and high dependence on individual skills and sampling conditions, as well as relying on the principle of increasing our knowledge of this disease and understanding the causes of creating and Its development (mentioned in the introduction), and the invention of new diagnostic methods as a complement or even alternative to the methods currently used have been of interest to many researchers in this field. The study of the pathogenesis and the attempt to find biomarkers of cervical cancer have led to the emergence of new ideas for early diagnosis and treatment [29].

Recent studies in the field of cervical cancer

Scientific information is focused on the initial diagnosis and targeted treatment of cancer. HPV induces metastasis and related events by affecting cellular signaling pathways. Human papillomavirus increases the expression of many cellular genes, including genes involved in reproduction and survival, the transition from epithelial to mesenchymal, substrate-independent growth, and oxidative stress [30]. Research on cervical cancer shows that changes in the function of several genes lead to abnormal proliferation and invasion of tumor cells.

Cervical cancer has a global prevalence and is the most common type of cancer in developing countries. It is the fourth most common cancer among women and annually more than 400,000 cases of this malignancy are reported in the world, which accounts for approximately 12% of the most common cancers among women [31]. Researchers point to several risk factors for cervical cancer. In a case-control study conducted in Mexico, factors such as the number of deliveries, the age of onset of sexual activity, and the use of oral contraceptives were examined. The prevalence of this cancer was 5 times higher in women who had given birth 12 times than in women who had given birth up to 3 times. It was also twice as common in women who started having sex after the age of 19 than in women who were under 15 when they started having sex. In addition, the use of hormonal contraceptives has been shown to increase the chances of developing cervical cancer [32].

According to many case studies, HPV infection has been identified as a major factor in the development of neoplasia and malignancy in the genital epithelium, and this is especially evident when there is a persistent infection with high-risk types of the virus [33]. Research over the past two decades has shown a strong association between cervical cancer and some types of human papillomavirus. In more than 90% of cases of invasive cervical cancer, the HPV genome is detected by molecular methods [34].

Pap smear test is used as a common test for screening patients around the world due to its relative ease and cheapness, but unfortunately, the number of false negatives in this test is very high [35]. HPV infections are usually asymptomatic, so methods to improve the screening process are needed to diagnose the infection. Epidemiological studies and efforts to develop vaccines require reliable methods to diagnose HPV genital infections and to determine the common genotypes in the infection [36].

Methods such as PCR, which detect the DNA of the virus, actually identify the cause of the infection, while cytological tests, such as Pap smear, identify the lesions and complications of the infection [37, 38]. PCR technique is considered one of the most sensitive methods for detecting HPV in genital tissues due to its ability to amplify viral DNA using specific primers, and its combination with sequencing as a confirmatory test increases its accuracy by 100%. Therefore, its use along with cytological methods can be significantly effective in increasing the resolution and accuracy of clinical examinations of patients [39].

Determining the common genotypes of the virus in a geographical area can also be very important in epidemiological studies and HPV vaccination development programs [40]. Experimental findings on the diagnosis of HPV genome in the samples indicate that the prevalence of carcinogenic types of HPV in patients studied in this study was 19.46%, which is consistent with the results of studies in some other regions of Iran.

In a study conducted in northern Iran, the presence of HPV in cervical cancer samples was shown to be 81.4%. This study shows that the frequency of HPV infection in cases of cervical cancer in Iran is also significant and comparable to other parts of the world [41]. Type 6 was one of the most common genotypes found in this study. Since cervical cancer usually occurs after 10-12 years after HPV infection, it is known as a complication that occurs in middle age. Findings show that in Yazd province, the highest prevalence of HPV in age groups (31-50 years) is 60%, while in many other countries, the highest prevalence of this virus is usually observed in lower age groups [21]. This difference is related to the onset of sexual intercourse.

In Iran, sexual intercourse usually begins with marriage and usually occurs between 20-30 years, but in Western societies, sexual activity usually begins after puberty. This could explain the incidence of cervical cancer in older Iranian women with HPV compared to many countries where the age of HPV infection is usually lower and in the age group of 21-39 years [33].

In some studies, some statistical populations are diagnosed in terms of patient pathology but show negative results in the HPV PCR test. There are several possible justifications for this: One is that the formation of malignant and cancerous lesions in these people was due to a carcinogen other than the HPV virus. Another is that according to a series of studies, the cause of false-negative results in PCR tests, especially in cases where pathological tests indicate the presence of malignant and invasive cancers, may be related to how the virus genome is replaced in the host cell chromosome [36].

According to one hypothesis, the cyclic genome of the virus is replaced in the chromosome of the host cell in such a way that it transforms the region of the gene that was the target of the PCR process and therefore changes the PCR results. Although the E2 gene region of the virus genome is usually degraded during the replacement process, in some cases the PCR primer binding sequences in the L1 gene region may be contiguous with the degraded regions of the virus genome, resulting in HPV DNA detection by PCR.

Another factor that can negatively affect the falsification of PCR results is the problems that arise in the process of preparation and extraction of DNA from formalin and paraffin-stabilized samples [22]. It has sometimes been observed that in studies using fresh tissue samples for PCR testing, the amount and percentage of HPV reported are usually higher than that of formalin-stabilized samples, which is probably due to abnormalities.

In the present study, the nested PCR technique was used to evaluate the frequency of the HPV genome. The results showed a significant relationship in the presence of the human papillomavirus genome. The present study, confirming the reports of some researchers, showed that the selection of an appropriate extraction method is important in improving the quality and quantity of DNA obtained and is very effective in the reliability of diagnostic results. In the DNA extraction stage, the cross-sectional preparation of tissue is very important. Cervical epithelial tissue has a high cell density. Therefore, the thickness of the cut should be appropriate and appropriate. If the thickness of tissue sections is not appropriate, PCR may interfere. If the cut thickness is low, the DNA concentration is low and if the thickness is increased, the protein degradation is incomplete and the impurity increases [16].

DNA extracted from samples is often high in concentration and contains factors that attenuate PCR, so it is best to use multiple dilutions of DNA in each sample for PCR to reduce the likelihood of false-negative responses. The presence of false-negative reactions can be due to the presence of many inhibitors in biological samples that have the potential to interfere with the PCR reaction. Inhibitors inhibit cofactor activity in PCR. On the other hand, these inhibitors can bind to the target site of Taq DNA Polymerase enzyme or directly inhibit the activity of this enzyme [11].

Therefore, these inhibitors can cause slightly erroneous results or false-negative results. In this case, the first step is to dilute the sample to reduce contaminants. In preparing the dilutions, it is necessary to observe the sterile conditions. In this study, we faced this challenge and this problem was solved by diluting the sample. The use of Nested PCR, which increases the sensitivity and accuracy of diagnosis, especially in low-titer samples of the virus, and also reduces the concentration of inhibitors that interfere with PCR performance due to its two-step concentration, can be very efficient [8].

High concentrations of primers with non-specific bonding cause dimers and non-specific products. Low primer also reduces bandwidth. Differences in the results of human papillomavirus genome identification in different studies may be due to the different populations studied, the sexual habits of the people in that community and the age of onset of sexual intercourse, the rate of human papillomavirus exposure, laboratory techniques and methods. Be used [42]. According to Table 3-4 (a), 3 men were simultaneously High risk, Intermediate risk, and Low risk, 8 were only Intermediate risk, 3 were Intermediate risk and Low risk and 3 were Low risk. According to Table 7, there were 34 low-risk women, 36 Intermediate risk, 7 Intermediate risk, and Low risk, 15 High risk, 3 High risk, and Low risk, and 3 High risk and Intermediate risk.

The largest and most comprehensive study to investigate the presence of the HPV genome in cervical cancer specimens was performed according to a standard protocol by the International Agency for Research on Cancer (IARC). About 1,000 women with confirmed cervical cancer from 22 countries around the world were included in the study. Frozen biopsy specimens of tumors in the central laboratory were examined for the presence of human papillomavirus DNA by PCR. The results of this study proved the presence of HPV-DNA in about 99.7% of the samples, which is a reason for the causal role of HPV in the development and progression of cervical cancer [43, 44]. This study was performed on 66 paraffin blocks of cervical cancer tissue by the Nested Multiplex-PCR method. Type 16 human papillomavirus was detected in 60% of the samples [45]. In several other separate studies conducted in Iran, the presence of the HPV genome in cervical cancer samples were reported to be 71.8%, 83.7%, and 77.7% [46].

In a combined analysis and a meta-analysis performed by the IARC, 3,000 and 10,000 cervical cancer samples were examined for the distribution of HPV types, respectively. Eight types of the most common types of HPV were identified in both series of studies, which are in descending order: HPV types 16, 18, 45, 31, 33, 52, 58, and 35. Among these eight common types, HPV-16 is the most common. Outbreaks and HPV-35 have the lowest prevalence. These eight types are responsible for about 90% of all cervical cancers worldwide [47].

Persistent infection with the human papillomavirus is the most important cause of the development and progression of cervical cancer, but only a small percentage of women infected with HPV develop cervical cancer. Therefore, there may be other risk factors for having an independent or boosting role of HPV in the occurrence of cervical cancer, such as having multiple sexual partners, initiating sexual intercourse at an early age, contracting the human immunodeficiency virus (HIV), smoking, oral contraceptives, and other pathogenic factors, although the exact mechanism of each is still unknown [48].

Therefore, it is necessary to study the molecular mechanisms of cervical cancer and the role of HPV in creating and facilitating the process of this disease [49].

CONCLUSIONS

Several types of vaccines have been proposed to control cervical cancer, some of which have been licensed by the World Health Organization. HPV vaccination is common in countries such as the United States and Canada. The structure of these vaccines consists of L1 and L2 viruses of the virus and they are made using the common epitopes 6,18,16,11 HPV. Given that some types of papilloma viruses have a specific regional prevalence and are also identified in cervical cancer; therefore, some researchers believe that epidemiological studies can be an effective aid in determining the appropriate structure of the vaccine. Therefore, in Iran, such studies will be very useful in selecting or designing a suitable vaccine.

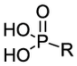
Abstract: *The identification of organophosphate (OP) compounds dates back to the 1800s. OPare largely used pesticides in the agricultural field and households but prior use as a chemical weapon was considered during wars. Their toxicity on humans has been previously studied and addresses both acute intoxication and low-level chronic exposure. Symptoms of acute exposure describe a cholinergic syndrome with bradycardia, miosis, confusion, fasciculations, tearing, sialorrhea, diarrhea, bronchorrhea, and bronchospasm. The intermediate syndrome causes paralysis of the gait muscles, neck flexors, and respiratory failure. Moreover, unrestricted access to OP has increased the rate of suicide, accounting for around 30% of cases, increasing concern about OP availability. Western countries have drastically restricted access to OP by imposing regulations regarding handling these hazardous substances, but efforts have to be made to globally reduce this struggle.*

Keywords: *organophosphates, pesticides, combat gases, bioterrorism, poisoning*

INTRODUCTION

Organophosphates (OP) are substances that contain carbon and phosphorus atoms in their structure (Figure 1), but not all compounds with this component inhibit acetylcholinesterase [1]. Depending on their chemical substrate, they can be divided into four classes with individual physical features. OP has been widely used as a pesticide, compounds being spread both in the agricultural field and in households [2].

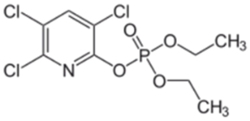
Figure 1: Structure of organophosphate compounds (ro.wikipedia.org)



Their specific physical and chemical characteristics determine the duration of the pesticide effect, as well as the duration of persistence on applied surfaces or soil [3]. As a result, the degradation mechanisms differ from one OP compound to another [4].

Out of the OP, chlorpyrifos (Figure 2), is the world's most widely used organophosphorus insecticide, being effective against mosquitoes, and lice, while dichlorvos has shown beneficial in controlling plant lice (aphids), flies or spiders [1,5].

Figure 2: Chemical structure of Chlorpyryphos (cen.acs.org)



Diazinon (Figure 3), a thiophosphate compound, is effective against silverfish, fleas or ants, malathion is indicated against mosquitoes, wasps or insects that affect fruit trees [1]. Parathion (Figure 4) is a broad-spectrum insecticide, but its use has been restricted due to its toxic effects [6].

In addition to their use as pesticides, ester OP compounds are used as flame retardants or plasticizers in various industries. They are utilized for coating electronic instruments, such as antifoams or adhesives [7]. The OP

esters are mixed with the other elements in the composition of the desired substances, without making any chemical bonds with them [8].

OP poisoning is a major cause of morbidity and mortality worldwide. Due to its widespread use in agriculture and domestic use, contact with OP substances has become very common. In countries where there are no imposed regulations on OP use in agriculture, the number of cases of intoxication is significantly higher [9].

A special aspect regarding the incidence of OP poisoning is their use as a method of suicide. Globally, this type of intoxication is considered one of the main methods of suicide, accounting for approximately a third of all cases, raising it as a top priority health problem [10].

HISTORY OF ORGANOPHOSPHATE COMPOUNDS – FROM DISCOVERY TO HAZARDOUS USE

With the perfection of ether synthesis methods by the chemist Alexander Williamson, the synthesis of organophosphates (OP) has been possible since the middle of the 19th century [11,12].

The initial discoverers of the OP class are traditionally considered to be the French chemist Philippe de Clermont and the Russian Wladimir P Moschnin, but the contribution of the Swiss Franz Anton Vögeli must not be forgotten [11]. In his laboratory, Gustav Magnus managed to synthesize two products resulting from the combination of ether with phosphoric acid [11]. Other sources claim that the Swedish Bo Holmstedt was the first to describe the structure of the first OP, namely tetraethyl pyrophosphate (Figure 5), in a letter to the French chemist Clermont [13].

However, there is evidence that indicates that several OP were synthesized by the French Jean Louis Lassaigne well before those mentioned above [13,14]. In the early 1800s, he succeeded to demonstrate the existence of phosphovinic acid, which was later synthesized by Jules Pelouze [12]. Later on, Anton Vögeli used these studies to elaborate on diethyl- and triethyl phosphate [11,12] (Figures 6 and 7).

Figure 5: Chemical structure of tetraethyl pyrophosphate (en.wikipedia.org)

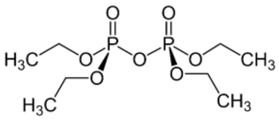

Figure 6: Chemical structure of Diethyl Phosphate (selleckchem.com)

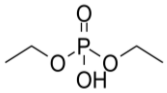

Figure 7: Chemical structure of Triethylphosphate (en.wikipedia.org)

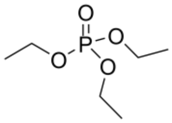
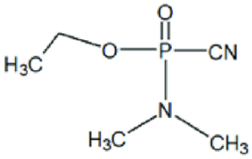


Although in recent research the French chemist Clermont has been invested with a major role in laying the foundations of OP, studies of the history of medicine indicate that W.P. Moschnin contributed to at least the same importance [15]. Moreover, there is evidence of joint activity of the two chemists in the same laboratory in Paris [13,15]. Despite being considered the parents of OP, Clermont and Moschnin were unable to understand and describe the effects of these substances [13]. After obtaining tetraethyl pyrophosphate, the first product that could inhibit acetylcholinesterase, Clermont's only description, obtained after tasting, distinguished that it is "a thick and sticky liquid, with an intense taste and a special smell" [11].

The chemists Ernst Ratzlaff and Adolf Schall identified, under the guidance of prestigious professor August Michaelis, a compound named diethylphosphoramidocyanate, similar to what would be called decades later "tabun"-diethylphosphoramidocyanate (Figure 8) [16].

Figure 8: Chemical structure of Tabun (researchegate.net)



Research on the effects of OP was subsequently continued, at the beginning of the 20th century, by the Germans Willy

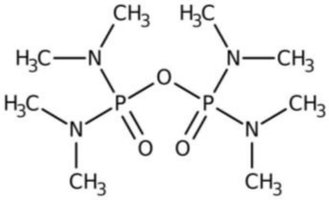
Lange and Gerda von Krüger, who first described the toxicity of these substances [17].

During the preparation of his doctoral thesis, Gerda von Krüger, together with his coordinating professor, Willy Lange, elaborated their most important scientific work: the description of toxic effects of OP, namely shortness of breath, photosensitivity, and disturbance of consciousness, which disappear within hours after ending exposure [17]. With the introduction of the Nazi regime, Willy Lange is forced to stop their study and reaches the United States, where he will devote himself to other research work [17].

The study of the toxic effects of OP was continued by the chemist Gerhard Schräder, who, in the attempt to obtain an OP-based insecticide, is exposed to it and needed medical care for several days [16]. When he returns to the laboratory, Schräder identifies the substance that caused the manifestations as ethyl-N-N-dimethylphosphoramido-cyanate, which he called “tabun” (from the German word "taboo") [16].

Throughout his activity Schräder successfully synthesized many OPs and created the first OP insecticide, octamethylpyrophosphoramide (Figure 9), marketed under the name E605 and used in agriculture [13]. With the end of World War II, this substance was taken over by the allied countries, where it was widely marketed under the name of parathion [13].

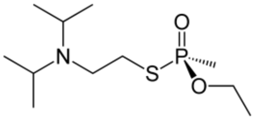
Figure 9: Chemical structure of Octamethylpyrophosphoramide (fischersci.com)



Although Nazi Germany secretly tried to create a chemical weapon based on OP, it has never been used on battlefields, despite repeated accusations from Stalin [13,18]. At the same time, other countries searched for chemical weapons based on tabun, sarin, or phosgene, but they were not used during World War II [13,18,19]. Although it has been proven that Japan used this type of weapon during World War II, it did not contain OP [19].

After the war, in the United Kingdom, the chemist Ranajit Ghosh, synthesized a new product called VX (Figure 10), thus creating a new class of OP (class V – from the English word "venomous") which was used as a chemical weapon [20].

Figure 10: Chemical structure of Vx (Wikiwand.com)



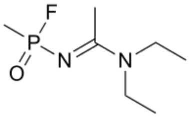
Meanwhile, the Soviet Union developed a similar compound VX, called VR or Russian VX (84). Despite international regulations regarding the use of combat gases (tabun, sarin, or phosgene), they have been used countless times during the First Gulf War between Iran and Iraq – tabun, Yemen – phosgene, Cambodia – phosgene, Angola – VX or Syria – sarin [21,22].

In addition to the armed attacks that used the combat gases, chemical terrorism has also developed, characterized by a series of attacks on the civilian population, the best known being the sarin attack on the Tokyo subway (Figure 11) which resulted in about 640 victims [23].

Figure 11: Sarin Attack in Tokyo (brittanica.com)

With the dissolution of the Soviet Union in the early 1990s, many documents were declassified, showing that during the Cold War, the Russian authorities secretly led a chemical weapon development program, called FOLIANT [20]. Thus it appears that VR served as a prototype for another class of OP called Novichok or class A [20]. This class of agents, with chemical weapon potential, came back to attention in 2018 when Russian spy Sergei Skripal and his daughter were attacked with a Novichok (Figure 12) compound [20].

Figure 12: Chemical structure of Novichok (chm.bris.ac.uk)



Beyond the development of chemical weapons, research continued to obtain insecticides that can be widely used. At the same time, the mechanism of action of OP has been discovered, as well as the possible antidotes that can be used in case of acute intoxication [13].

OP production continues to grow, with more than 200,000 tones of insecticides being used each year in the European Union [10]. According to Eurostat statistics between 2011 and 2016, pesticide consumption was steadily increasing, and only six countries reported a decrease in pesticide sales [24]. The largest decrease was in Denmark, at about 50%, followed by Ireland, Italy, Malta, Portugal, and Romania [24]. There are also countries in which the sale of pesticides has increased, the spike was in Austria (over 25%), followed by France, Slovakia, and Hungary [24].

The country with the highest pesticide production and consumption worldwide is China, where both imports and exports grow annually [10,25]. In the United States, the tendency to increase pesticide consumption is maintained, the most used compound being glyphosate [26]. In Brazil, pesticide consumption increased by more than 200% from 2000 to 2013 [27].

ORGANOPHOSPHATE TOXICITY AND CURRENT REGULATIONS

Toxicokinetics refers to the behavior of toxic substances in the body from the moment of penetration to elimination. Absorption, distribution, metabolism, and elimination of OP pesticides depend on the physical properties of the compounds, but also the dose involved [28]. Most OP compounds are fat-soluble and not ionized, which promotes rapid absorption [29]. OP is rapidly absorbed orally and by inhalation. The fat solubility of OP compounds favors the crossing of lipid membranes in the body, so they have a wide systemic distribution in all organs [29,30].

In the case of acute intoxication with pesticides, the onset of clinical manifestations depend on the characteristics of the agent involved, and the mode and duration of exposure [31].

Manifestations of OP poisoning are mainly characterized by a parasympathetic vegetative dysfunction, induced by the accumulation of acetylcholine [31]. According to the distribution of cholinergic receptors, specific signs and symptoms of acute intoxication correspond to the stimulation of nicotinic and muscarinic receptors [32].

Classically, manifestations of acute exposure are described as a cholinergic syndrome characterized mainly by bradycardia, miosis, confusion, fasciculations, tearing, sialorrhea, nausea, diarrhea, bronchorrhea, and bronchospasm [33].

The main features of the intermediate syndrome are paralysis of the gait muscles, neck flexors, cranial nerves, and respiratory failure caused by diaphragmatic paralysis and intercostal muscles [34].

Late poisoning manifestations manifest as polyneuropathy and occur more rarely than the intermediate syndrome [35]. Nevertheless, endocrine and metabolic dysfunction may occur even after low-dose OP exposure [36,37].

Considering that at present OP is widely used, we try to limit consumption by strict regulations regarding the quantities and concentrations applied to agricultural crops or in households [38,39]. For example, if in the early 1990s the number of pesticides exceeded 10 kg/ha in many Western European countries, European Union standards currently limit these quantities below 4.6 kg/ha [39]. Moreover, the use and marketing of OP are subject to the rules of the Rotterdam Convention which assessed, based on national reports, the risks associated with them [40]. In addition, the Convention had done a classification of these substances, which led to the development of worldwide use and labeling rules. Last but not least, substances considered to be at high risk for the general population were banned by the committee of the Convention [40].

Furthermore, in the European Union, there are regulations developed by the Parliament and the European Council, whose application has been mandatory in all member countries (Regulation (EC) No 1185/2009 of the European Parliament and of the Council of 25 November 2009 on pesticide statistics) [40].

The United States reinitiated regulatory processes of OP exposure since raising the possibility of OP’s risk to children. Thus, programs targeting to assess exposure risk to pesticides were made as well as considering the menace of co-exposure to pesticides with similar toxicity mechanisms [41].

The United Kingdom has revealed neuro-psychiatric disorders in participants of the Gulf War that were designated as OP poisoning. Moreover, identifying increasing rates of depression in farmers exposed to OP made new regulations eliminate OP and carbamates off the market [41].

Despite European efforts to decrease the accessibility to OP, Japan has only imposed restrictions on the most toxic compound, namely methamidophos. Regarding other OP compounds, indications are of correct use without imposing limitations in agriculture or domestic fields [42].

CONCLUSIONS

The discovery of OP compounds involved various scientists that would first describe their action, namely inhibiting acetylcholinesterase, and then describe toxic effects [43]. OP toxicity proved useful in acting as pesticides in agriculture but the risk of developing a chemical weapon based on OP compounds has dominated wars [44].

Exposure to OP is a significant public health problem associated with long-term repercussions like affecting human brain development [9]. Despite an incompletely known toxicity mechanism, several countries have issued strict rules regarding OP use. Although Romania is one of the countries that has reported a global decline in pesticide trade, the increased accessibility of this type of product for people untrained in handling and using it suggests the need for stricter regulations.

Futurology and monitoring in the field of virology to deal with emerging diseases

Mohammadreza Baqerkhani[1], Ali Soleimanzadeh[2], Hadi E.G. Ghaleh[1], Mahdieh Farzanehpour[1]

Abstract: *Every year we see many changes in the world around us. One of these changes is the climate and weather, and it could be one of the reasons for changing behaviors between humans and animals, which could cause zoonotic diseases. We usually face new diseases that infect a growing population leading to a pandemic. Different reasons are leading to an increase in the emergence of new infections. Some of these diseases can be associated with zoonotic diseases and the diverse world of viral genetics and its failures. Furthermore, properties like mutations and also unknown effects of these mutations on the virulence of the agents make it challenging to trace new diseases. As we know, preventing emerging diseases is inevitable and viral diseases are dangerous, and some viruses can spread quickly and cause an endemic or pandemic. As was noticed during the recent pandemic, the need to study emerging diseases in the field of virology has become more and more apparent to us. In this review, we want to look at how we could monitor and control these diseases with new approaches and what should be done when a disease emerges. Moreover, we will investigate risk factors, ways to deal with emerging viral infections, new treatments that make the condition better when a person gets infected, and the future of these diseases. We will also study the ways to deal with pandemics with the new generations of vaccines.*

Keywords: *emerging-disease, viral disease, futurology, vaccination*

BACKGROUND

The world has witnessed various emerging infectious diseases (EIDs) that reemerge and cause multiple health and financial issues. For instance, in 2010, an unusual clinical image showed severe inflammatory syndrome which was along with vascular conditions similar to transient ischemic attacks or venous thromboembolism. There were several reports of this issue, and almost ten cases were recognized. The patients having underlying autoimmune diseases or hematologic malignancies were the primary targets for this condition [1,2].

Emerging infectious diseases are recent phenomena that affect humans with a high rate of spreading in different geographical areas. We have experienced more than 50 EIDs in the last 40 years. Most of these infections are re-emerging after a period, which has led to the adoption of the term "emerging and reemerging infectious diseases." The term is used for infectious diseases that occur once in a region or among a population. It appears again with more virulence or with resistance to the drugs once used to eradicate them. We should also note that the re-emergence of infectious diseases happens at a higher occurrence rate than the initial emergence [3].

Various new and reemerging infectious diseases are threatening people all over the world, inflicting higher financial costs to societies along with increasing the risk of mortality. Some of the most recent infectious diseases include pneumonia, SARS, swine flu (H1N1), influenza, malaria, tuberculosis (TB), cholera, hepatitis, meningitis, food-borne gastroenteritis, chikungunya, Ebola virus diseases, campylobacteriosis, and salmonellosis. The most recent infectious disease threatening people all over the world is SARS-COV2 (Covid-19) [3–6].

There exist more than 50 EIDs in the world at the moment with varying levels of threat to public health. These infectious diseases can target human beings, animals, and plants. Studies indicate that climate change can also lead to the emergence of many of these diseases. Thus, controlling

climate change and environmental factors can help control and eradicate infectious diseases[7].

Population growth has a fundamental role in the spread of diseases. It is also concurrent with the rise in speed and rate of travel across the earth which leads to the rapid dissemination of pathogens across the globe. This is partly due to globalization which has increased international trade, migration, and reduction in travel costs. Furthermore, an increase in leisure travels to previously unknown destinations is also one of the main factors in exposing people to various infectious agents [2,6–8].

During the last 20 years, researchers have encountered various species which were resistant to drugs, and some of them are classified as species that are resistant to several drugs, including methicillin-resistant Staphylococcus aureus, vancomycin-resistant enterococci, multidrug-resistant or extensively resistant tuberculosis, carbapenemase-encoding Gram-negative bacteria, and extended-spectrum β-lactamase E. Coli. These are considered emerging pathogens and can rapidly disseminate among hospitalized patients and people of varying ages; hence, they require considerable attention [2].

These infectious diseases are a source of frustration among the general public. Notably, the emergence and re-emergence of all these diseases are dependent on the economic and geographical position of the region [3,9]. The good news is that most of these diseases are controlled through new chemotherapeutic methods, but that is not the case with all of them, since some of these agents are not controlled due to unknown etiology and lack of proper management methods [3,10,11]. Scientists have cited various problems as the reason for the onset of these infections, among which one can note population, improper food-processing methods, lack of awareness about hygiene measures, and problems in water distribution systems and sewage pipelines. Furthermore, the production of ineffective antimicrobial agents by pharmaceutical companies is another cause that makes it difficult to manage these infectious diseases. Infections acquired in the hospital and pathogens which are resistant to various drugs are also issues that can make the result of treatments uncertain [3,12,13].

Countries need to change their object of focus from healthcare and prevention to research on the determinants of health and primary healthcare provision. Political empowerment and creating a global initiative to increase the capacity of the health sector in developed and developing nations is another alternative that government officials need to consider to stop the spread and emergence of various infectious diseases [14,15].

Various drastic changes have been experienced during the last three decades in clinical virology laboratories. Direct diagnosis of the virus in clinical specimens is one of the main issues noticed in the last decades, which means the demonstration of virus particles (including viral antigens and nucleic acids) [16,17]. The application of new methods and reformulation of the old ones, demand for an easier test with higher accuracy and multiple applications, the trends existing in developing countries along with the detection of new concepts regarding microbial interactions are among the factors shaping molecular assays, development of diagnostic approaches, and changes in the interpretation of data obtained in the laboratory [18].

A considerable number of emerging infectious diseases are the result of zoonotic agents, and in some cases, vector-borne viruses are responsible for their emergence. Although resistance to antimicrobial drugs is another troubling issue, it is less likely to have bacterial or fungal pathogens as the cause of a pandemic [19].

In this study, we want to clarify how emerging diseases can be monitored and controlled and how we can deal with them in times of occurrence to stop or prevent the occurrence of a pandemic or endemic disease.

MONITORING AND OBSERVATION

Our local environment and global landscape is changing all the time. Due to the higher error rate of virus enzymes replicating their genomes, viruses containing RNA can adapt themselves to different conditions. That is the reason for the higher rate of emergence and re-emergence of diseases that are caused by RNA viruses [14]. For instance, the pandemics caused by influenza virus strains are caused by viruses that reside in host animals before infecting humans. Humans, horses, pigs, birds (domestic and wild), and sea mammals are among the species that can be infected with the influenza virus.

The present century has witnessed the death of over 20 million people in different countries due to Spanish influenza, which had a higher prevalence compared to HIV [18]. The ways to recognize the pathogens and distinguish test positive individuals from the negative ones are the first steps to controlling and monitoring emerging diseases.

New technologies and approaches to microbial interaction

CRISPR and next-generation sequencing (NGS) are among the recent technologies emerging in the market. A single reaction in NGS can parallel sequence a large number of DNA templates. It is quite fast and cheap at sequencing the complete genome of many microbial samples. Virology has various applications such as management of viral infections, figuring out the infection sources, investigating the immune response of the host, and selecting the proper intervention and treatment strategies [18,20,21].

NGS makes use of three methods to sequence the genetic material of the virus. The first one is identical to the Sanger method and is done through amplification and sequencing of the target. The second method is done through nonspecific amplification of the genetic content of the sample before NGS. The third approach enriches the genetic material of the virus and makes use of NGS to sequence them subsequently. NGS has higher throughput besides being fully automated and can find the genome mutations causing drug resistance. It is also able to target several viruses at the same time. The added benefit of NGS is that it can detect both known and new microbes despite being pathogen or commensal. NGS is mainly used for the detection of different drug-resistant variants of HIV and HBV in clinical virology.

The advantage of detecting the undetectable variants is not yet clear, but the evidence obtained from resistance tests of patients with low levels of virus and rare mutations (including patients with HIV) shows that they will have a great influence on routine clinical practice and platform for nucleic acid detection based on nucleic acid amplification and Cas13a-mediated cleavage of a reporter RNA which enables the detection of the target in real-time [22–24] SHERLOCK is among the best techniques which equal PCR essays in terms of sensitivity. It is used to detect one or several RNAs residing in the microbial strains. One of the best features of SHERLOCK is its ability to be combined with non-PCR methods used for amplification. SHERLOCK is widely used for the detection of nucleic acids from other viral threats, including the dengue virus and Zika. SHERLOCK is also important in terms of commercial usage since its reagents can be lyophilized and reconstituted on paper.

Researchers can also run it on body fluids without the need to be extracted before and provides the results in less than two hours [18,25,26]. DETECTOR (DNA endonuclease targeted CRISPR trans-reporter) is another technology that is similar to SHERLOCK in using Cas12a. The mere difference is that it works on DNA, and shows unspecific collateral single-stranded DNA cleavage activity once it recognizes the target sequence. DETECTOR has attomolar sensitivity in detecting DNA. Furthermore, it is widely used for detecting human papillomavirus 16 and 18, which are two human papillomaviruses that have a high tendency to neoplastic transformation. DETECTOR is easy to use and much faster than the existing methods of human papillomavirus detection. Moreover, you do not need to provide any special equipment for conducting DETECTOR. Hence, it can be considered a useful platform for clinics that lack resources, and it is a good option for conducting molecular diagnostics rapidly [18,27].

Previous multiplex assays combined the detected viruses according to various parameters, including primer and reagents, amplification reaction, sample processing compatibility, etc. Hence, the tests were mainly based on analytical methods.

Novel methods are capable of detecting a wide range of germs and viruses with the same clinical manifestations, entry method, and tissue tropism. This is the main reason for multianalyte tests known as syndromic tests.

There are some proprietary panels produced by pharmaceutical companies which are dedicated to infections of gastro intestine, respiratory system, central nervous system, and the infections that are transmitted sexually [18,28–30] Biocontainment laboratories that are located far from EVD treatment centers usually use RT-PCR as their main diagnostic test. Recent approaches make use of Point-of-Care ELISA-based assays for VP40 matrix protein. It provides considerable operational advantages and leads to the timely isolation of positive cases. Hence, it is a great tool to clear suspect cases with higher accuracy and sensitivity compared to the methods used earlier. However, the role it plays in field conditions is uncertain [31,32]

The existence of a centralized infrastructure for sequencing in areas that have a higher biological diversity which acts as the beginning sources of new human infections can help fast and timely detection of emerging pathogens. Furthermore, these centralized infrastructures can act as hubs to send resources to unknown locations in cases of new outbreaks. This infrastructure has the potential to search the environment regularly to figure out the spectrum of viral strains and species existing within phylogenetic families that can infect humans. Furthermore, it could be used for high-throughput sequencing to define all existing viruses [19].

An initiative of WHO named Research and Development (R&D) Blueprint works on decreasing the period from the initial reports of a public health emergency to the provision of test kits and diagnostic methods, treatments, and vaccines to rescue people’s lives and prevent the initiation of the health crisis. It also takes severe emerging diseases into account that lack any type of countermeasures to prevent their expansion. It was at the request of 194 Member States in May 2015 that WHO asked a group of specialists to develop a Research and Development (R&D) Blueprint for Action to Prevent Epidemics.

It was on 31 December 2019 that reports were sent to WHO about several pneumonia cases without a definite cause in Wuhan City, Hubei Province of China. Chinese authorities identified the coronavirus disease (COVID-19) as the causative agent on 7 January 2020 [4]. The R&D blueprint started its activity on the day it was informed of the pandemic to work on diagnosing, vaccinating, and therapeutic measures for eradication of the virus [4]. The infectious agents occurring for the first time pose various challenges due to a lack of knowledge about their identity, epidemiology, and pathogenesis, which are the case invariants of influenza or COVID-19. It is also difficult to identify the zoonotic reservoir which makes it more challenging to foretell the time, place, and possibility of an outbreak [33]. Most of the reports regarding emerging diseases are from developed countries. The United States accounts for more than a third of reports about emerging diseases [34] which shows the important role of geographical location in the emergence and spread of an infectious agent.

CONTROL, TREAT, AND FUTURE STUDY

Probable approaches to control and treat

Gene-based antigen-delivery technologies are the best methods to fight EIDs; however, some of these methods have not received the required licenses to be used in human medicine. Furthermore, in times of crisis when time plays an important role, these technologies can provide vaccines in the shortest time possible based on the information obtained from target-gene sequences compared to other methods which require the virus to be isolated and grown along with considerable containment [19]. Interference in the transmission of the virus from animals to human beings can help control zoonosis which is possible via vaccines that are self-disseminating. These vaccines can act on insects, animals, and also environmental reservoirs of the virus.

These methods work by the replication of the existing vectors of the virus that are engineered for the expression of the disease’s antigens. They are also used in cases when clinicians want to target specific groups of animals. The objective of animal vaccination is to keep pathogens of the disease in the animal reservoirs to prevent them from infecting humans. There are various issues including costs, possibilities, and the ensuing safety concerns that should be kept in mind during this method which are necessary for controlling the sources of these pathogens. Moreover, it is not possible to predict which animal pathogen can cause disease in humans. It should be noted that the usage of a CMV-based vector to vaccinate apes was suggested as a way to curb the transmission of the Ebola virus to people. The same method was also effective in protecting the animals against death [44,45].

Hospitals are the first place to have a measure to control the transmission of viruses. The staffs are at a higher risk in the initial outbreak; however, providing most centers with personal protective equipment and kits has prevented further transmission. It was also difficult to reduce the risk of transmission during the burial rituals. The main difficulty stemmed from making burial consistent with social and familial norms [31]. The world has witnessed different emerging and reemerging infectious diseases which have threatened it in terms of security, economy, and biodefense [46,47].

There were several diseases in the past few years including H1N1 (2009-Mexico) [48], SARS (2002-China) [49], MERS (2012-Saudi Arabia) [50], Ebola (EBOV) (2013-Africa) [51], Lassa virus (2018-Nigeria) [52], Zika virus (2015-Brazil) [53], and the COVID-19 pandemic (2019) [54] has made different scientists eager to devise strategies for quicker prevention, treatment, and/or controlling these epidemic viruses [44]. The number of fatal cases (case fertility rate) due to emerging and reemerging infectious diseases was high during the specified time, which indicated the need for immediate action to prevent their spread [44,55].

Various factors, including globalization, urbanization, travel, commerce, climate change, and the increasing elderly population are also influencing factors in the emergence of these diseases. Zoonotic diseases are also on the rise due to increasing contact with zoonotic sources. Traveling has also been on the rise due to rapid and comfortable means of traveling, and it makes it increases the distribution of pathogens all over the world. Furthermore, the elderly are far more at risk of these infections, which leads to a higher mortality rate. All these issues affect the way pathogens are distributed all over a previously endemic zone [56,57]. Due to the nonexistent nature of licensed antiviral drugs to prevent or treat emerging viruses, the treatment method is restricted to care and fluid- and electrolyte therapies. However, these prevention methods are also absent in most developing countries [58].

Cytokine-storm

Cytokine storm is regarded as one of the most lethal immune syndromes with a quick-spreading ability and highly activated T cells, natural killer cells, and macrophages. It also causes overproduction and release of many inflammatory cytokines and chemical mediators through immune or non-immune defense cells. Induction of hypercytokinemia, also known as cytokine storm (CS), is the main cause of the high fatality rate in immunocompetent individuals. It can also engender different pathological side effects such as shock, damage to the tissues, sepsis, the failure of several organs of the body, and edema. In some cases, lack of attention to these symptoms can lead to death.

Moreover, cytokine storm is concurrent with hemorrhagic fevers caused by a virus, and these immunopathological conditions can be due to several viruses including Lassa, Crimean, Congo hemorrhagic fever, Ebola, and Dengue fever (DF), and Marburg viruses [58,59].

Currently, there is no standard treatment to cure cases of cytokine storm and we lack drugs that are approved specifically to treat cytokine storm. Corticosteroids were not successful in treating cytokine storm in clinical testing. Furthermore, non-steroidal anti-inflammatory medicine was not able to treat cases of cytokine storm while used besides antiviral drugs. Hence, further randomized control is required in this regard. Some experiments are being conducted on new treatment options and they are in the preclinical testing stage. We hope that these methods prove effective in treating cytokine storm [58]. Although oseltamivir was being used in some countries of South Asia during the infection of the area with the HPAI virus, there is no report about how effective this method was. Furthermore, these clinical studies did not show a considerable reduction in the number of death cases due to using oseltamivir. The reports indicated that the rate of survival in patients receiving oseltamivir equaled 30% (13 of 34); while the survival rate in untreated cases was 25% (4 of 16). Hence, it can be said that the efficacy of oseltamivir treatment was dependent on timely administration. In cases when the treatment was within 5 days after the initiation of the symptoms, the rate of survival was 53%; however, postponing the oseltamivir administration to 6 days reduced the rate of survival up to 26% [60,61]. S

everal anti-inflammatory drugs (being administered alone or in combination with other therapies) have been assessed for the treatment of cytokine storm in influenza infections. However, it was seen in one of the studies that the utilization of anti-inflammatory drugs as a single treatment to cure cytokine storm comes with various challenges. The same study showed that curbing cytokine production by glucocorticoids did not lead to any form of protection for the mice infected with HPIA (A/Vietnam/ 1203/04 H5N1) [62]. The results obtained from another study indicate that combining COX-2 inhibitors with zanamivir has significant effects on survival since it acts by stopping the emergence of apoptosis and decreasing cytokine dysfunction [63,64]. Sphingosine-1-phosphate-1 receptor (S1P1R) agonists have been used for both suppressions of cytokine storm and treatment of pathogenic influenza virus infection in mice. The protection level was higher in this method in comparison to oseltamivir, and the rate of survival equaled 50%. However, the protection was the highest in cases receiving oseltamivir and AAL-R, and the reports delineate the survival rate equaling 96%. Being licensed, these drugs can help us in combating various pandemics, and they can be used to suppress various viruses including MERS, Ebola, and SARS which are the prominent causes inducing cytokine storm [65].

One of the novel approaches to treating cytokine storm involves the down-regulation of main signaling pathways or genes that are responsible for the regulation of various host responses including apoptosis or inflammation. The signaling pathway named C-Jun N-terminal Kinase plays a role in different mechanisms such as apoptosis, inflammation, and proliferation. The reports indicate that they are activated during the infection and replication of the influenza A virus [66]. Treatment of mice with short-term heat (39°C for 4 hours) led to a significant increase in HSP70, and it also increased the amounts of cytokines TNF-α, IFN-β, IFN-γ, and IL-6. The study showed that 57% of treated mice were alive after 14 days of being infected with HPVI. It is suggested that the positive effects of heat shock treatment on HPAI are correlated with the increased expression and protective effects of HSP70, which leads to transient down-regulation of the over-expressions of pro-inflammatory cytokines in the lungs [67]. It also makes interferon and TNF-alpha be expressed in response to infection and activates pathways to secrete specific proteins and antiviral cytokines. The results show that macrophages can be a good biomarker to assess the severity of influenza infection [68,69].

Following pathology identification, it is necessary to develop preclinical models to study the interactions between the virus and the host and select vaccination volunteers to define its features. Furthermore, the identification of the epitopes is required for the guidance of the vaccine and it has a role in the production of antibodies and lowering Nabs. All in all, these lead to antibody-dependent enhancement of the infection caused by the virus. Furthermore, the agencies, governments, and companies working in the field should share data and collaborate to have a strategic approach to the prevention of the next pandemic threats [70,71]. Due to the lack of effective drugs or vaccines to work against the COVID-19 pathogens, social distancing is the only method to hinder the spread of the virus. Hygiene measures are also necessary to prevent contact with patients. Using soap and water to wash hands along with using alcohol-based sanitizers are among the other preventive measures in the absence of effective drugs. It is noteworthy that COVID-19 pathogens can survive on surfaces for up to a few days;

hence, using disinfectants is usually effective in eliminating the pathogens residing on the surfaces [72].

The first step during a pandemic or endemic disease is to limit the contact between populations to stop transmission between human beings. In some cases, the diseases could be zoonotic and the animal vectors should be avoided. As said earlier about viral emerging diseases, we know that viral diseases mostly do not respond to drug-based treatments; hence, vaccination is the most effective choice to control emerging diseases [54].

Challenges in dealing with emerging diseases via vaccination

As noted earlier, vaccination remains the only effective method to stop the spread of viral emerging diseases. Vaccines can cause protective responses in the body against pathogens and reduce the causes of morbidity and mortality. Rapid vaccine production is essential to manage the outbreak and prevent the spread of the viral agent [44]. The history of using the vaccine to deal with viral emerging diseases dates back to 1938 when the U.S. army soldiers received influenza vaccines during World War II [73].

Vaccines have higher efficacy than other treatment options; hence, it is necessary to develop vaccines for all emerging infectious diseases. However, vaccine production is not readily possible for some viral infections due to the unknown identity of emerging pathogens, inadequate animal models, cost and time required for production, licensing, and global distribution, to name a few [74].

Vaccines are tested on young, healthy volunteers. This method was used for Dengue and Influenza virus; however, there should be an accepted treatment option if any problem occurs. Licensure and final approval of the vaccines are other issues that need to be considered. Rapid development and administration of a safe and effective vaccine is another challenge [75,76].

Long-lasting protection by making the body produce antibodies against the pathogens in question is the criterion to measure the efficacy of vaccines. The study conducted by Nakaya et al. analyzed the antibody responses following influenza vaccination on day 28 vs. 180. They emphasized finding pathways that were related to the waning or persistent reaction of the antibody [77].

The phrase ‘synthetic vaccinology’ is used in cases where only sequencing data are enough to start designing vaccine antigens and reagent production. Recent developments and advances in the field of protein engineering, understanding of the assembly of virus-like particles (VLPs), and the identification of other self-assembling molecules that improve immunogenicity by optimizing antigen display make it easier to adjust the vaccine-induced immune responses to specific antigens [19,78].

Some viruses can escape the trap of the immune system. The same strategies cannot be used for all cases of virus emergence, and there need to be new strategies for antigen design and formulation, pathway, sequence, and the timing of administration in some cases, such as extreme genetic plasticity and antigenic variability (HIV and Influenza virus), persistent infection and latency (HIV or Herpesviruses), or multiple distinct serotypes (rhinoviruses). Removing these biological obstacles of 'difficult' viral pathogens can provide methods to use in pre-pandemic vaccine development or rapid vaccine development in cases of emerging viral pathogens [19].

There are two types of mRNA vaccines developed so far. The first is a conventional non-replicating vaccine, and the other is a self-amplifying vaccine. A mature mRNA molecule is produced by the IVT method conducted a plasmid of the of a DNA template, which has the sequence for RNA polymerase that is dependent on DNA. It includes an open reading frame that can encode the required antigen, the 50 and 30 flanking UTRs, the terminal poly(A) tail, and the 50 caps. The host's cellular machinery translates the vaccine in vivo after receiving it and provides the corresponding post transnationally modified antigen. This is the process through which the vaccine mimics being infected naturally in vivo. These vaccines can activate the immune system by attaching to receptors, thus creating immune responses. The produced mRNA vaccines can make the body immune for a long time against various infections caused by viruses such as Ebola, Zika, influenza, Dengue, and other viral diseases [44,74,79].

Adenoviruses are mostly used viral vectors for priming the immune system. They can lead to both cellular and humoral responses. In clinical trials with adenoviruses, the existence of an anti-vector can challenge the vaccine response. To prevent immunity, the vaccine platforms for human beings are usually taken from adenoviral vectors obtained from animals. In some cases, rare species are also used for these purposes. Two vaccines are made of viral vectors: Imojev and Dengvaxia. The former is a vaccine used for JEV and the latter is a Dengue vaccine. Both these vaccines are produced by Sanofi Pasteur. Chimeric YFV is used as a vector in both of them. They work by propagating chimeric viruses inside the cell culture [44,80].

There are also protein-based recombinant vaccines that contain the immunogenic protein of the pathogen it aims to target. The production of these vaccines requires the identification of the pathogen. Bioreactors are used to produce these vaccines on a large scale depending on the posttranscriptional pattern of modification required by the use of heterologous expression systems, like yeasts, insects, bacteria, mammalian cell lines, or plants.

These vaccines are safe due to the lack of genetic information derived from the pathogen, and there is no need to live pathogen manipulation during the manufacturing process. They are suitable in times when a quick response is needed to an epidemic condition. It is because the production process can begin after the virus genome has been sequenced, and there is no need for virus isolation. Vaccines based on protein can be obtained during the production of recombinant virus subunits (SUVs). It is also possible to administer them along with adjuvants for enhancing the immune reaction of the host against the recombinant viral antigens [44,81].

CONCLUSION

It is estimated that zoonosis accounts for about 60% of diseases stemming from infections. The source of most infectious agents is wildlife, and increasing contact with wildlife can increase the occurrence of infectious diseases. Climate change is another issue leading to vector-borne diseases; however, it needs to be further evaluated to see the exact influence of climate alterations on the occurrence of the agents causing infections. Recently, various platforms are used to design vaccines which include viral-vector vaccines, nucleic acid vaccines, and recombinant protein-based vaccines.

Studies have revealed the overlap between animal and human ecosystems as one of the reasons for COVID-19 to pass the species barrier. Hence, there is a need for coordination with veterinary experts and the submission of laws to control the animal trade.

Our suggestion is the establishment of working groups and scientific consortia to govern the design process of vaccine antigens. The produced antigens should lead to the production of cross-reactive antibodies. These working groups should also look for novel vaccine administration methods to directly target the agents affecting immunity. Each pandemic enhances our scientific knowledge regarding the induction of cytokine storm by viruses. Identification of novel therapies for the treatment and control of infections requires enhancing our knowledge about the complicated interaction between antiviral immune responses of the host and the ability of the virus to change these responses and lead to immune dysfunction.

It is predicted that the world will witness the emergence and re-emergence of various zoonotic and mosquito-borne viruses in the future. The natural mutation will be the process through which these viruses evolve, and they will pose a real threat to public health. It will be difficult to protect against them due to the lack of proper therapeutic procedures including vaccines or drugs. Hence, it is necessary to be prepared for them and work on novel approaches for the treatment and control of these pathogens. In particular, the development of methods targeting the route taken advantage of by viruses provides the opportunity for effective treatment methods in different viral strains.

Almost all outbreaks have been with the nosocomial transmission, and there are several cases of transmission in the hospital. Hence, healthcare sector workers should be among the first groups receiving vaccination when a pandemic or endemic occurs. Our study showed that zoonotic diseases play the main role in emerging diseases, especially emerging viral diseases. Hence, the role of the veterinarian as the frontline confrontation with emerging diseases is quite clear in preventing the occurrence of a pandemic. Because there is no effective cure for viral emerging diseases other than prevention and control, all nations should have a group of veterinarian scientists to control and deal with the animal reservoirs and vectors to prevent a pandemic [19,78,82–88].

Acknowledgments
We would like to thank the “Clinical Research Development Center of Baqiyatallah hospital” for their kindly cooperation.

Authors’ Contributions
Dr. H. Esmaeili and Mr. M. Baqerkhani both developed the concept, design, and definition of the intellectual content of this article, Dr. A. Soleimanzadeh and Mr. M. Baqerkhani both developed the literature search, data acquisition, data analysis and statistical analysis of this article. Dr. M. Farzanehpour and Mr. M. Baqerkhani both developed manuscript preparation for this article. Dr. M. Farzanehpour developed manuscript editing and manuscript review. Dr. M. Farzanehpour is in charge to take responsibility for the integrity of the work as a whole from inception to published article and is designated as 'guarantor'.

Ethics approval and consent to participate
This study was executed under the supervision of the ethical committee of Baqiyatallah University of Medical Sciences, Tehran, Iran (ethical code IR.BMSU.REC.1399.555 (.

Conflict of interest statement
The authors declare that there are no conflicts of interest.

Gene therapy by using stem cells in the treatment of hepatitis

Hadi E.G. Ghaleh[1], Masoumeh Bolandian[1], Ruhollah Dorostkar[1], Bahman J. Kondori[2], Farshad N. Asiabani[1], Akbar G. Alvanagh[3], Mahdieh Farzanehpour[1]

Abstract: *Chronic hepatitis can resolve spontaneously or progress to more advanced stages, i.e. fibrosis, cirrhosis, and liver cancer, respectively. Two million deaths each year are attributed to liver diseases globally. Chronic liver disease and cirrhosis comprise 11th position in leading causes of death worldwide. Viral infections account for the etiologic factor of most cases of hepatitis. Almost the only available way for the treatment of end stages of hepatitis is liver transplantation. The biggest problem with this therapeutic approach is the number of liver transplant donors is less than the number of recipients. Therefore, more advanced methods must investigate. Recently, gene therapy by the utilization of stem cells yielded promising results in clinical and preclinical investigations to the treatment of liver diseases. Novel genome editing tools such as TALENs and CRISPR/Cas9 consider as powerful genome correction approaches and can employ for iPSCs gene editing. This paper highlights the various aspects of gene therapy through stem cells for liver diseases*

Keywords: *gene therapy, stem cell, hepatitis, CRISPR/Cas9*

INTRODUCTION

The liver is the real organ in the body complicated in the bile production, metabolism, toxins elimination, and immune responses, and several disorders of metabolism are of hepatic basis. There are many different types of liver diseases, comprising hepatitis, alcoholic liver disease, fatty liver disease, hereditary disease, cirrhosis, fibrosis, etc. These may result in liver failure and lead to irreparable liver impairment. Even though the liver is capable to repair itself, while the injury is beyond repair it is hazardous and lethal to patients [1]. Hepatitis consider as a condition of the presence of inflammation in the liver that divides into two categories, i.e. acute hepatitis and chronic hepatitis. The latter is defined as lasting for more than six months. This inflammation can resolve spontaneously or progress to more advanced stages, i.e. fibrosis, cirrhosis, and liver cancer, respectively [2-4]. Liver diseases are responsible for nearly 2 million deaths whole the world yearly. Chronic liver disease and cirrhosis ranked as 11th and 5th leading causes of death worldwide and for the non-Hispanic AIAN population of the United States, respectively [5, 6]. Most cases of hepatitis attribute to viral infections as an etiologic factor. Other important leading causes include infectious agents except for viruses, alcohol, drugs, and autoimmune reactions. The only available way for the treatment of end stages of hepatitis is liver transplantation. One of the main problems of this way is the discrepancy in the number of liver transplant donors and recipients. Furthermore, the recipient's immune system could reject the grafted organ [7]. Consequently, different methods must be considered and explored. Recent progress in gene therapy opens a promising new window to the treatment of a broad range of diseases. In the procedure of gene therapy, to reduce the symptoms or completely cure a disease, genetic material is delivered to a patient [8]. This approach tries to sustain express a transgene, as well as minimizes adverse side

effects. One of the best profits of gene therapy is that a single treatment is sufficient, therefore is no need for repeated administration [9, 10]. Gene therapy utilizes in various fields such as the treatment of cancers, monogenic diseases, infectious diseases, heart diseases, neurological diseases, eye diseases, etc. [11, 12]. By 2017, about 2600 clinical trials initiate that some of which approves. The most common types of gene therapy include gene replacement therapy, CAR (Chimeric antigen receptor) T-cell therapy, and gene editing. In recent years, stem cells, as one of the top topics in the broad range of advanced scientific research, have attracted the attention of many researchers and become a good tool for gene therapy [13]. In fact, in vitro stem cell culture is straightforward and they can differentiate into hepatocytes and new liver cell sorts. The results of novel scientific investigations in stem cell gene therapy open new horizons in the treatment of hepatitis [14, 15]. It hopes that shortly, these approaches will enter clinical practice. There are several sources for stem cell therapy of liver diseases that are summarized in Table 1 [16-22].

Table 1: Sources for stem cell therapy

Liver-Derived Stem Cells	
	• Adult liver stem cells (oval cells) • Fetal liver stem cells (hepatoblasts)
Bone Marrow-Derived Stem Cells (BM-DSCs)	
	• Hematopoietic stem cells (HSCs) • Mesenchymal stem cells (MSCs)
Annex Stem Cells	
Embryonic Stem Cells (ESCs)	
Induced Pluripotent Stem Cells (iPSCs)	

In this review, we discuss gene therapy via manipulated stem cells for the treatment of hepatitis.

ANIMAL MODELS AND THERAPEUTIC GENE TRANSFER BY USING STEM CELLS

Today, animal models are considered a key tool in research fields. They have played a key role in the advancement of medical sciences, especially in cell and gene therapy for hepatitis. Although many efforts make in this regard, however, there are still differences between animal models and humans [23-26]. Among animal models, mice can be a good choice for the study of hepatitis pathophysiology as well as the development of novel, safe, and efficient drugs. A big problem is the mice cannot be infected with hepatitis viruses. Several strategies were developed to solve this problem: Humanized chimeric, transfection, and transgenic mice [27]. Gene therapy by using stem cells is a new version of previous gene therapy approaches. In this procedure, therapeutic genes are inserted into stem cells, and then the genetically modified stem cells are delivered to the patient's body [28, 29].

Currently, outstanding achievements in the development of stem cell therapy approaches have brought new hopes in treating liver diseases. Many studies have been carried out in this field and emerging evidence suggests that the utilization of stem cell-based-gene therapy is a good way for the treatment of liver diseases, especially hepatitis [30-32]. For example, a study conducted by Zhu et al. on a mouse model showed that the use of bone marrow-derived mesenchymal stem cells (BM-MSCs) led to the immigration of these cells to the liver that boosts immune system performance, and improves liver damage caused by (concanavalin A) ConA [33]. Gilsanz et al. in their experiment, examined the effect of human/rat adipose-derived mesenchymal stem cells (AD-MSCs) injection to the liver parenchyma of rats and observed that the biochemical serum analytes of the liver, hepatomegaly, splenomegaly, and ascites have remarkably improved [34]. Masalova et al. used modified mouse mesenchymal stem cells (mMSCs) of DBA/2J (H-2d) mice that expressed 5 non-structural proteins of the hepatitis C virus (HCV), including NS3, NS4A, NS4B, NS5A, and NS5B. Then the analysis of innate and adaptive immune responses showed this approach drives high phagocytosis, lymphocyte proliferation, and type I/II interferon production, as well as, IFN-γ secretion, Immunoglobulin G (IgG) production [35].

ADVANTAGES AND DISADVANTAGES OF STEM CELL-BASED THERAPY

The aim of stem cell-based therapy for liver disease is to substitute disease cells with healthy ones and let the healthy cells be efficient. Around the world, several research groups are conducting the expansion of stem cell-based therapy for liver diseases. The objectives are to recognize stem cell varieties that are appropriate for the applications and transplantation. To attain these aims, scientists should tackle significant challenges. Because adult tissues compose of many diverse cell sorts, the identification and trying to pinpoint the stem cells are the tasks for experts. Afterward, the cell isolation from the tissues, inducing cells to differentiate into favorite cell types is an additional impediment. As well as, cells might be rejected by patients' bodies after grafting, which is an additional concern [36].

One of the most significant advantages of Induced Pluripotent Stem Cells (iPSCs) over other stem cells is its application as autologous stem cell therapy with the minimum risk of rejection induced by the immune system of the host (allogeneic immune rejection). In addition, these cells can differentiate from hepatic cells and have the capability of self-regeneration and pluripotency [37, 38]. Observed that using Yamanaka factors including Oct3/4, Sox2, c-Myc, and Klf-4 can reprogram mouse fibroblasts into iPSCs [22]. On the other hand, iPSCs can be differentiated to hepatocyte-like cells (HLCs) and then delivered to the diseased liver, ultimately recovering their proper function [39].

Recent work demonstrates that gene transferring, genome editing, three-dimensional (3D) culture, and extracellular matrix approaches improved hepatic differentiation of human iPS cell-derived hepatocyte-like cells with more than 90% purity and a satisfactory level of liver functions that are comparable to primary human hepatocytes [40].

INDUCED PLURIPOTENT STEM CELLS AS PATIENT-SPECIFIC MODELS TO ASSESS EXOGENOUS GENE DELIVERY

Human iPSCs are a possible basis for the treatment of end-stage liver disease. Some research has stated the improvement procedure for differentiation of human iPSCs into the hepatocytes. Hannan et al. defined a procedure that organized the differentiation of human iPSCs into a close-homogenous population of HLCs by 25 days [41].

One of the critical aspects of gene therapy is selecting an appropriate method for transgene delivery to the target. A variety of vector systems are available for this purpose. For the genetic material transfer to the target cells, both viral and non-viral vectors can be utilized. The transduction efficiency of non-viral vectors is lower than viral vectors that confer a shorter duration of transgene expression. Properties of an ideal vector are high capacity, low antigenic potential, high transduction efficiency, providing conditions for targeted and controlled transgene expression, and being safe. Both ex vivo and in vivo gene delivery approaches are used for the liver.

The ex vivo process involves the removal of single cells from a host and transfers to the outside the body, gene transduction in vitro (gene modification), and then transmission back again to the body. The ex vivo has more aggression for the patient and more cell-specificity than the in vivo method [42, 43]. Interferon-alpha (IFN-α) gene transferring to the liver by using a sustained expression shuttle vector may lead to long-term production of IFN- α in the liver. In a study, researchers examined the effect of an adenovirus expressing IFN-α in preventing viral hepatitis in mice [44]. It has been demonstrated the anti-HBV ZFNs can disturb viral DNA in cell culture without any cell toxicity and off-target cleavage [45]. The TALENs are similar in arrangement to the ZFNs. Bloom and colleagues showed that the Anti-HBV TALENs have nearly 87% targeted mutagenesis and 80% HBV gene expression reduction in a murine model [46].

GENOME EDITING STEM CELLS

Genome editing in iPSCs generates a population of differentiated cells that are valuable for disease modeling, drug improvement, genetic editing, and finally, for autologous cell therapy. New advancements in the genetic engineering area introduce several strategies such as transcription activator-like effector nucleases (TALENs), zinc finger nucleases (ZFNs), and clustered regularly interspaced short palindromic repeats (CRISPR)/CRISPR associated system (Cas9) that are powerful genome editing tools for iPSCs gene correction. When the gene-editing process is complete, the iPSCs can differentiate into HLCs and, consequently, engrafted to the target [47, 48].

As noted above, viral and non-viral vectors are available for the delivery and expression of a transgene to the liver. Viral vectors showed the best results in the previous investigations. The viral vectors divide into two groups: integrating (adeno-associated viruses or AAVs, lentivirus, retrovirus) and non-integrating vectors (adenovirus or Ad, poxvirus, herpes simplex virus, or HSV). Transgene expression stability and infection transmission rate of integrating viral delivery systems is satisfactory, but there is a risk of insertional mutagenesis. If an integrating viral vector inserts in an aberrant location on the host genome, leading to high expression of a proto-oncogene or inactivation of a functional and essential gene, which, in turn, it may have unintended consequences like malignant cell transformation. For example, 5 patients in clinical trials performed to treat severe combined immunodeficiency (SCID), developed leukemia that the cause of this phenomenon consider to retroviral-mediated gene transfer [49]. Collectively, researchers should be careful about integrating vectors because there is a risk of mutation in these vectors. Unlike the integrating viral vectors, the non-integrating viral vectors as adenoviral, poxviral, and herpes simplex viral vectors cannot integrate into the chromosomal DNA and remain in the nucleus as an episomal form [50, 51].

TALENs and ZFNs strategies have a severe defect: off-targets side effects that lead to low specificity; additionally, the massive size of TALENs and epigenetic variations damaging access to the preferred chromosomal site are substantial challenges for use in a clinical setting, but recently discovered CRISPR/Cas9 technology show higher efficiency [52]. CRISPR/Cas9 genome editing is a regular RNA-mediated acquired protection mechanism found in some prokaryotic organisms [53]. It has quickly become the most hopeful genome editing tool with the pronounced potential to modernize biomedical treatment [54].

CONCLUSION

The treatment of liver diseases has been complicated, which needs and requests for novel and improved knowledge. Liver inflammation can resolve spontaneously or progress to more advanced stages, i.e. fibrosis, cirrhosis, and liver cancer, respectively. These three late stages were considered irreversible phenomenon. Still, recent advancements in gene therapy, stem cell therapy, and genome editing open a good road to treating liver diseases.

Regarding the other types of liver diseases, it is possible to provide potentially effective treatments. Although there are many obstacles, especially in the preparation of different systems in terms of safety and efficiency, different gene delivery pathways, the immunogenicity of vectors used, and improving cells type specificity, still, the potential to correct genetic defects and increase the quality of life in patients is very promising. It was merging advanced gene-editing techniques with methods for using viral and non-viral vectors that can revolutionize medical sciences and cure many disorders. Improving these methods in the future could target many polygenic conditions, and the ability of these methods to regulate gene expression could provide more effective treatments for a wide kind of disease.

Among stem cell types, IPSCs technology has provided unique chances to study, inhibit and treat a variety of human diseases, especially liver diseases. The ability of these cells to regenerate themselves and differentiate has led to the total production of hepatocyte-like cells for transplantation and research. For example, these differentiated cells can be used in cell therapy to repair, replace, and regenerate liver tissue efficiently. In addition, IPSCs consider valuable resources for evaluating drugs interactions, metabolism, and toxicity of the drug and biological factors [55-57].

However, there are still barriers and limitations to using these cells that need to address. For instance, evidence on IPSC cell lines and reprogramming procedures and their differentiation into hepatocyte-like cells should be enhanced to increase their effectiveness.

Gingival involvement of oral non-tumoral mucosal diseases

Elena C. Tofan[1], Ioanina Părlătescu[1], Elena Coculescu[1], Şerban Ţovaru[1], Carmen Nicolae[1], Bogdan I. Coculescu[2]

Abstract: *Gingival conditions are frequently encountered in dental clinical practice and they can raise diagnosis and treatment problems. The diagnostic is variable from normal conditions to autoimmune diseases or even malignancy. Some of them cause disturbances such as pain, burning sensation and have an impact on patient's quality of life.*

INTRODUCTION

Although oral cavity is an area easy to explore by visual exam, there is a large variety of conditions and disorders which can be encountered. We present a general overview of gingival lesions frequently associated with oral mucosal diseases. Dental plaque-induced gingivitis and all gingival enlargements (reactive or tumorous with benign, cystic or malignant variants) are not the subject of this article.

DEFINITION OF SPECIFIC TERMS AND LESIONS

The gingiva is a "first line" mechanical barrier defined as the keratinized mucosa that covers the teeth and the alveolar bone. The periodontium is made of gingiva with the alveolar bone, periodontal ligament and cementum. The mucogingival junction separates the gingiva from alveolar mucosa [1]. In healthy persons the gingiva has a pink color (Figure 1), or it can have pigmented areas depending on the individual skin color (Figure 2).

Histologically, gingiva is composed of a thick stratified, keratinized epithelium and the underling connective tissue made of collagen and elastin fibers, fibroblasts, melanocytes and immune cells [2]. The epithelium cell-to-cell adhesion is done through desmosomes and adherence junctions while the adhesion to the basement membrane is done by hemidesmosomes and focal contacts [3].

Superficial lesions affect epithelium and underlying connective tissue. Depending on the clinical appearance, evidenced by visual examination, they can be divided into: keratosis or white lesion (Figure 3A and 3B), atrophic (Figures 4A, 4B, 4C), ulcers resulting from vesicles (Figure 5A) or bulla (Figure 5B).

The gingival diseases are presented in the periodontal diseases classification elaborated by Armitage in 1999 [4] which is universally

CLINICAL FEATURES AND THE BASIC THERAPEUTICALLY APPROACH OF ORAL MUCOSAL DISEASES WITH GINGIVAL INVOLVEMENT

We reviewed and summarized the clinical characteristics of the most frequent oral diseases. The oral manifestations of general diseases cover a large range of conditions (Table 2). The mainly local signs usually affects more than one mucosal area, so the gingival lesions must be interpreted in the whole context.

Table 1. The gingival diseases classification [4]

Periodontal diseases classification. Section gingival diseases		
A. Dental plaque-induced gingival diseases	1. Gingivitis associated with dental plaque only 2. Gingival diseases modified by systemic factors 3. Gingival diseases modified by medications 4. Gingival diseases modified by malnutrition	
B. Non-plaque-induced gingival lesions	1. Gingival diseases of specific bacterial origin 2. Gingival diseases of viral origin 3. Gingival diseases of fungal origin	
C. Gingival lesions of genetic origin	1. Hereditary gingival fibromatosis 2. Other	
D. Gingival manifestations of systemic conditions	1. Mucocutaneous disorders	1) lichen planus 2) pemphigoid 3) pemphigus vulgaris 4) erythema multiforme 5) lupus erythematosus 6) drug-induced 7) other
	2. Allergic reactions	
E. Traumatic lesions (factitious, iatrogenic, accidental)	1. Chemical injury 2. Physical injury 3. Thermal injury	
F. Foreign body reactions		

Oral lichen planus is a disease with chronic evolution and immune mediated pathogenesis [5]. The clinical signs and symptoms are variable depending on the lesions associated [2]. The lesions are multiple, associated, merged and coexist and symmetrically distributed. The gingival involvement, commonly encountered in these patients is described as desquamative gingivitis. This shows various lesions from white, keratotic to atrophy, ulcerations and bullae. The diagnostic criteria universally accepted includes the histological confirmation (with hydropic degeneration and band-like T-cells infiltrate), although there are microscopic features similar to other mucosal diseases [6].

The therapy is not curative but it intends to control acute lesions and symptoms. The agents used cover a large spectrum of drugs: topical or systemic corticoids, hydroxychloroquine, azathioprine, mycophenolate mofetil, methotrexate, dapsone, thalidomide, biological agents etc. [6].

Mucous membrane pemphigoid is a chronic autoimmune blistering disease which presents subepithelial vesicles and bullae. Any area of the oral mucosa can be affected. The gingival lesions present as desquamative gingivitis which simulates oral lichen planus and are noticed in 60% of cases [6]. The diagnosis is established by histopathological analysis and direct immunofluorescence which shows along the basal membrane linear deposits of immune-globulin IgG, IgM, IgA and complement [6]. The therapy is mainly long-term immunosuppressive treatment used local and systemic.

Table 2. General data on oral mucosal diseases, clinical features [1-3]

Oral conditions	Disease	Oral mucosa manifestations
Autoimmune diseases	Oral lichen planus	Variable presentation, generally symmetrical lesions (reticular, popular, plaque form, atrophy, ulcers, bulla)
	Pemphigus vulgaris	Small intraepithelial bulla and secondary erosion
	Mucous membrane pemphigoid	Desquamative gingivitis, shallow ulcer after multiple blisters affecting the oral mucosa
	Linear IgA dermatosis	Annular vesicular-bullous lesions
	Allergic reaction to dental materials and/oral health products	Variable clinical features: inflammation, reddish or white areas
Infectious diseases		
Viral	Primary herpetic infection	Ulcerative lesions following short duration vesicles
	Secondary herpetic infection	
	Herpes zoster	Unilateral ulcers following vesicles, located along nerve distribution, mainly in older patients
Bacterial	Necrotizing ulcerative gingivitis	Painful, purulent ulcers of the gingival papillae; mostly in teenagers and young adults
Traumatic lesions	Caused by excessive tooth brushing	Ulcers, atrophy and keratosis
	Mucosal burn caused by substances held in close contact for a long period of time	
	Local radiotherapy	
Pigmented lesions	Rasial pigmentation	Pigmented areas on the gingiva
	Melanotic macule	
	Metallic tattoo	
White lesions	Leukoplakia	Predominantly white lesion of unknown or tobacco etiology

Oral pemphigus vulgaris is a lifelong autoimmune bullous disease which affects the epithelium with autoantibodies directed against the desmosomal cadherine – desmoglein 3 causing acantholysis and blistering [7]. Oral mucosa is the initial site of the lesions in 80% of the patients [7]. The painful, irregular-shaped erosions and blisters affect the buccal mucosa, the tongue and gingiva. In these patients the desquamative gingivitis shows ulcers following bullae. The diagnosis is established by clinical features, histopathology, immunopathology, and serology. Direct immunofluorescence shows intercellular deposition of immunoglobulin G and complement 3 [7]. Treatment is complex and includes a variety of immunosuppressive and anti-inflammatory steroids in order to get disease control.

In patients with desquamative gingivitis there is an increased risk periodontal tissue breakdown mainly caused by the plaque deposits and the pain associated with tooth-brushing [8].

Herpetic oral viral infection is caused by two types of herpes simplex virus. The primary infection which affects mainly children or young adults shows a wide range of manifestations varying from an extended oral vesicular-ulcerative eruption to a reduced, asymptomatic condition [2, 9]. The primary eruption may be associated with general signs and symptoms such as fever, malaise, lymphadenopathy and dysphagia. The secondary infective episode usually involve gingival mucosa and the hard palate. The lesions are vesicles which break quickly and leave painful ulcers. These heal in 7-10 days without scars [9] in healthy and immunologically competent patients. Infections diagnosed early show a good response to antiviral medication. Also local symptomatic suspensions will ease the discomfort in both primary and secondary herpetic eruption.

For **pigmented lesions of the oral cavity**, more than for other conditions the diagnosis is challenging even for an experienced clinician [10]. On the gingiva the physiological pigmentation and the melanotic macules are frequently seen but this does not exclude a melanoma or Kaposi sarcoma diagnosis. The physiological pigmentation is caused by an increased melanin pigmentation of the basal layer or incontinent melanin and/or melanophages in the superficial lamina propria and the melanotic macules are a result of a increased melanin production from the basal melanocytes. In these cases, the diagnosis is appreciated after size, shape, or color, location together with the anamnestic data [10]. Generally a biopsy is needed to determine a definitive diagnosis and to exclude risky conditions.

Oral leukoplakia is defined as a predominately white lesion of the oral mucosa, lesion of questionable risk having excluded (other) known diseases or disorders that carry no increased risk of cancer [11]. It can be met in any area of the oral mucosa, including gingiva. At present about this lesion, the literature states that neither histology nor clinical factors can reliably predict the behavior [12]. Proliferative verrucous leukoplakia is one of the most aggressive form described which shows a predominant gingival involvement.

CONCLUSIONS

These gingival conditions can share similar clinical features which may lead to misdiagnosis or underdiagnosed situations. Dentists and general practitioners need to be familial to the gingival disorders. In general a definitive diagnosis is based on biopsy of the lesional tissue but also the anamnestic data should be taken to account.

VARIA

Golden hour of sepsis: Can we do more?

Sebastian Dogaru[1], Ciprian Jurcuţ[1], Caius B. Teușdea[1], Alexandru Rocşoreanu[2], Florea Purcaru[2]

Abstract: *Introduction: Sepsis is a life-threatening organ dysfunction due to a dysregulated host response to an infection1 and also an important worldwide health problem. Recent progresses in understanding pathogenesis are reflected in increasing emphasis put on time (Sepsis Update 2018 decreased the time for diagnosis and treatment from 3- 6 hs Sepsis-2 to 1 hour). The aim of the study was to combine an early warning score (increased sensitivity- NEWS2) and a biomarker (increased specificity- presepsin) in order to detect earlier an acute illness (infection) before becoming life-threatening.*

Materials and methods: It was a retrospective, single-center observational cohort study of 125 consecutive patients who were diagnosed with systemic inflammatory response syndrome between July 2016 and July 2018 at Emergency Department of "Dr. Carol Davila" Central Military Emergency University Hospital, Bucharest, Romania in order to determine sooner, which patient will further develop a sepsis. We used the area under receiver–operator characteristic curves (AUC) to assess the overall discriminatory power of NEWS2, MEDS and presepsin in detecting sepsis, septic shock and the probability of death on admission and compared them with combined scores between NEWS2 and presepsin.

Results: Using a combined score and a simple algorithm, the NEWS2 score had changed (12,8%) for 16 patients. For 10 out of 95 (10,52%) without sepsis and 6 out of 30 (20%) of septic patients, more points were added to NEWS2 meaning that more septic patients were diagnosed before an infection become life-threatening

Conclusions: In the present study, we have tried to assess the impact of a monitoring score and a rapid POCT biomarker, in a condition when time is of critical importance. Using a verified early warning score, NEWS2, with increased sensibility and low specificity and presepsin, POCT biomarker with increased specificity, we diagnosed sepsis earlier in a number of cases.

Keywords: *sepsis, early warning score, NEWS2, combined score, presepsin*

INTRODUCTION

Sepsis is a life-threatening organ dysfunction due to a dysregulated host response to an infection [1] and also an important worldwide health problem. Nowadays the global sepsis estimates are more than double than previous calculations, with 11 million sepsis deaths and 48.9 million incident sepsis cases in 2017 with a global trend of decreasing sepsis [2]. Although Sepsis-3 definition is designed to put a diagnosis in prehospital settings, battlefield and Emergency Department (ED) on arrival there is much to be done to further improve diagnostic of patients with sepsis. The specificity of the Sepsis-3 criteria is great, but sometimes the sepsis diagnostic is put too late for a specific patient.

Rapid clinical evaluation on arrival in ED and as soon as possible paraclinical evaluation are realized with POCT (point of care testing) devices which allow a more rapid targeted response (complete blood count, acid-base analysis, targeted biomarkers, etc.) to gain time for the patient and to prevent and fight against further deterioration of a patient in a not an optimal state. Sepsis-2 [3] emphasized the fact

"Dr. Carol Davila" Central Military Emergency University Hospital, Bucharest, Romania
[2] University of Medicine and Pharmacy, Craiova, Romania

that time management is of critical importance. Early targeted therapy and management bundle put an algorithm at hand for doctors and 2018 Sepsis update [4] indirectly stressed out that rapid medical intervention is paramount because what it should have been done in the first 3-6 hours, from that moment on, it must be done in one hour. For greater accuracy and tailored treatment more exhaustive laboratory analysis usually arrive in at least 30-40 minutes.

By 2015 over 36 Early Warning Scores were used and evaluated for accurately forecast the prognosis [5]. Developed as specific tools, in different environments (different wards, ED, ICU), some scores are nowadays obsolete or of limited use [5, 6] but some are still used and revised (NEWS2).

A possible research direction in sepsis might be to combine an early warning sign/score with increased sensibility, low specificity and a specific biomarker which will increase the specificity to buy time for the patient and ultimately to save more lives with increased cost-results efficiency.

Conceived in 2012, verified on different wards for several years and revised in 2017, National Early Warning Score 2 is nowadays used in United Kingdom with great success [7].

Used in different environments, presepsin is one of the biomarkers which passed the proof the time, as a valuable tool in POCT, being used for more than a decade now [8, 9, 10, 11, 12, 13]. Presepsin increases in patients developing infections in a severity-dependent manner [14, 15, 16]. Previous studies showed that presepsin levels performed when used for early diagnosis, risk stratification and prognosis [17, 18].

The aim of the study was to find new ways in which to combine these recently developed tools, an early warning score (NEWS2) and a specific biomarker (presepsin) in order to diagnose more cases of severe infections, before developing sepsis, preventing further deterioration of an already altered patient with multiple comorbidities. The proposed score is easy to calculate, rapidly available and allowed us to markedly decrease the time for intervention for patients with altered medical status before becoming life-threatening.

MATERIAL AND METHODS

Study design

This was a retrospective, single-center observational cohort study of 125 consecutive patients who were diagnosed with systemic inflammatory response syndrome between July 2016 and July 2018 at Emergency Department of “Dr. Carol Davila” Central Military Emergency University Hospital, Bucharest, Romania in order to determine sooner, which patient will further develop a sepsis. We developed a simple algorithm for earlier diagnose of sepsis and compared the results with Sepsis-3 criteria, NEWS2 and MEDS scores. All patients were above 18 years old and have agreed to sign the informed consent. The study was approved by the ethical committee at “Dr. Carol Davila” Central Military Emergency University Hospital, Bucharest, Romania.

Blood sample analysis

Presepsin concentrations were measured using a chemiluminescent enzyme immunoassay (PATHFAST™ Presepsin), performed on the PATHFAST point-of-care analyzer (Mitsubishi Chemical Medience Corporation, Tokyo, Japan). Measuring range is 20–20,000 ng/L; manufacturer's URL (95th percentile) is 320 ng/L. Correlation between heparinized and EDTA plasma was Y = 1.00× + 1.53 (r=0.999, n=23) [19].

Developing a tool for earlier diagnosis of sepsis

National Early Warning Score (NEWS) 2 is recommended by the NHS (National Health System) UK to determine the degree of illness of a patient, to prompt critical care intervention and recommends the NEWS 2 in the following settings: Emergency (for initial assessment, serial monitoring and assessment for triage), ward (for initial inpatient assessment and serial monitoring), prehospital (for communication of illness severity to receiving hospitals). Respiratory rate, hypercapnic respiratory failure/room or supplemental O_2, temperature, systolic BP (mmHg), pulse (beats per minute) and consciousness are assessed.

In order to try other combination of NEWS2 and PSP we have obtained other scorings to better predict the prognosis and earlier detection of sepsis.

We have created a new score NEWS2PSP: for PSP between 0-1000 pg/ml we granted 1 point; between 1000-2000 points=2 points, and so on. Adding those values to NEWS2 score lead us to the new score NEWS2 PSP.

Another compounded score was tested: for PSP<200 pg/ml we have given 1 point, 2 points for PSP=200- 300 pg/ml, 3 points for PSP=300-500 pg/ml, 4 points for PSP=500-1000 pg/ml and 5 points for PSP>1000 pg/ml. The new score was NEWS2PSP2.

NEWS2PSP3 resulted from granting 1 point if PSP>1000 and 0 points if PSP<1000.

Granting 0 points for PSP<5000 pg/ml, 1 point for PSP=5000-10000 pg/ml and 2 points for PSP>10000 and adding these points to NEWS2 lead us to NEWS2PSP4.

Statistical analysis

Descriptive statistics was used to summarize the study population. Baseline and follow-up characteristics were described by means and standard deviations (SD) or by median and interquartile range (IQR) for continuous variables, as appropriate, and by percentages for categorical variables. We performed Chi2 statistics or Fisher's exact tests when appropriate for qualitative variables, and the Wilcoxon/Mann–Whitney test for continuous variables with skewed distributions to compare baseline patient characteristics and study outcomes. Categorical variables are presented as counts and percentages. We used the area under receiver–operator characteristic curves (AUC) to assess the overall discriminatory power of NEWS2, MEDS and presepsin in detecting sepsis, septic shock of the probability of death on admission. The IBM SPSS version 20.0 software (IBM Corp., Armonk, NY, USA) was used for statistical analysis.

RESULTS

There were 125 consecutive patients which were considered to have SIRS (systemic inflammatory response syndrome) and included in the study. When 2 or more SIRS criteria were found, presepsin (PSP) was assessed. From these 30 were diagnosed as having sepsis (Sepsis-3 definition, with 2 or more qSOFA criteria) and 11 were diagnosed as having septic shock. During the study 27 patients have died from different causes, some of them being sepsis or septic shock. The mean age was of 70.88 years with standard deviation of 15.74 years; they ranged from 18 to 96 years. Of the total study population, 79 (63.2%) were men. Table 1 provides the baseline characteristics demographic data, the calculated scores, selected comorbidities and the site of infection.

Table 1: Baseline characteristics, used scores, selected comorbidities and the site of infection

Demographics	All patients (n=125)	Sepsis (n=30)	Septic shock (n=11)	Exitus (n=27)
Age (mean, SD)	70.888 (15.74406)	73.4666 (15.3139)	72.2727 (15.3391)	75.6296 (14.4277)

GCS= Glasgow Coma Scale, qSOFA= quick Sequential Organ Failure Assessment, NEWS2= National Early Warning Score 2, MEDS= Mortality in Emergency Department Score, PSP= presepsin

Patients who met the Sepsis-3 criteria (2 or more qSOFA points) were treated accordingly to the current guidelines for sepsis. Only 30 patients were diagnosed with sepsis and 11 with septic shock.

Table 2 shows the Area Under the Receiver Operating Characteristics and confidence intervals for the different scores and compound scores.

NEWS2 9.7±2.9, MEDS 14.0±3.0 and PSP (presepsin) 3582.8±4380.1 showed increased values for sepsis with statistical significance for NEWS2 $p<0.001$ MEDS $p<0.001$; of note the statistical significance for PSP was $p=0.043$. For sepsis NEWS2 has the best AUROC (Area under ROC) 0.962

(95%CI 5.54-7.51), MEDS 0.875 (95%CI 4.39-7.36), PSP 0.603(95%CI 41.32-2559.17) according to Sepsis-3 criteria as depicted in Figure 2. ROC curves are the same for septic shock NEWS2 0.974 (95%CI 6.11-9.74), MEDS 0.913(95%CI 4.39-9.3) and respectively for PSP 0.626 (95%CI 1526.19-2330.88) (Figure 3).

Table 2: AUROC and 95%CI calculated for different combined scores in sepsis, septic shock and mortality

	Sepsis		**Septic shock**		**Mortality**	
	AUROC	**95%CI**	**AUROC**	**95%CI**	**AUROC**	**95%CI**
NEWS2	0,962	5,54- 7,51	0,974	6,11- 9,74	0,670	0,79- 3,85
MEDS	0,875	4,39- 7,36	0,913	4,39- 9,3	**0,762**	2,55- 6,01
PSP	0,603	41,32- 2559,17	0,626	-1526,19- 2330,88	0,561	-454,79- 2184,34
NEWS2PSP	0,z924	6,36- 9,45	0,949	5,66- 11,20	0,656	1,21- 5,39
NEWS2PSP2	0,953	5,69- 7,84	**0,975**	6,31- 10,19	0,676	0,94- 4,17
NEWS2PSP3	0,956	5,95- 7,65	**0,975**	6,22- 9,96	0,672	0,90- 4,03
NEWS2PSP4	**0,971**	5,69- 7,65	0,972	6,07- 9,76	0,670	0,82- 3,91

Figure 1: Receiver-operating characteristics (ROC) curves for NEWS2, MEDS, PSP and for derived scores (NEWS2PSP, NEWS2PSP2, NEWS2PSP3, NEWS2PSP4) in sepsis (AUROC 0,971 %95 CI 5,69- 7,65 for NEWS2PSP4)

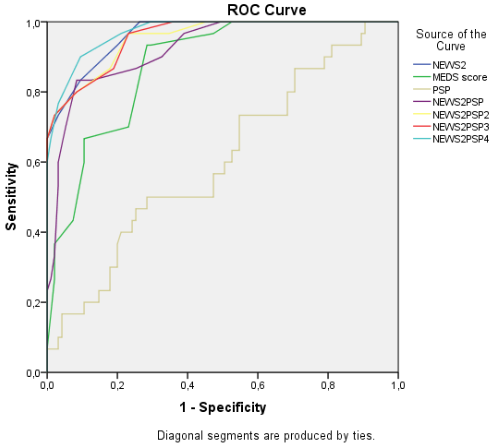

Figure 2: Receiver-operating characteristics (ROC) curves for NEWS2, MEDS, PSP and for derived scores (NEWS2PSP, NEWS2PSP2, NEWS2PSP3, NEWS2PSP4) in septic shock (AUROC 0,975 %95 CI 6,31- 10,19 for NEWS2PSP2 respectively AUROC 0,975 %95 CI 6,22- 9,96 for NEWS2PSP3)

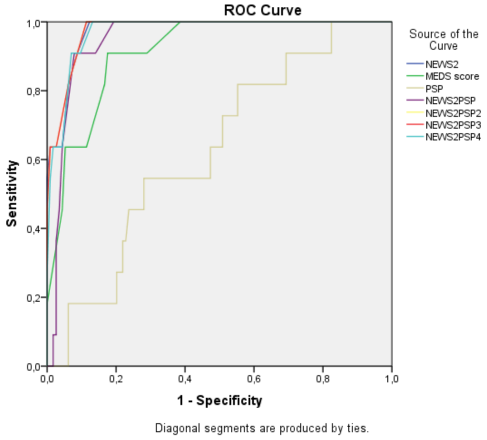

Figure 3: Receiver-operating characteristics (ROC) curves for NEWS2, MEDS, PSP and for derived scores (NEWS2PSP, NEWS2PSP2, NEWS2PSP3, NEWS2PSP4) in mortality (AUROC 0,762 %95 CI 2,55- 6,01 for MEDS score)

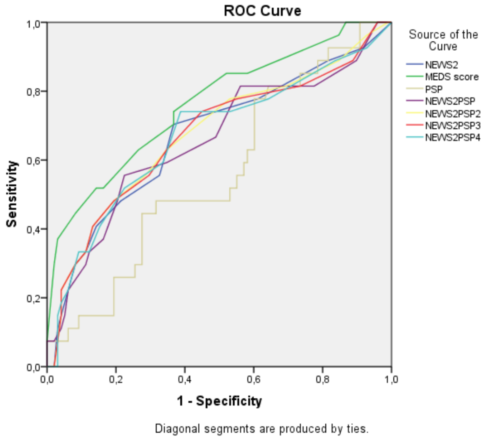

We created a new score, NEWS2PSP, transforming PSP values as follows: between 0-1000 pg/ml = 1 point; 1000-2000 pg/ml = 2 poits, and so on; adding these points to NEWS2 score resulted the new score NEWS2PSP; AUROC for sepsis and septic shock were not superior to NEWS2: AUROC NEWS2PSP in sepsis 0.924 (95%CI 6.36- 9.45), in septic shock 0.949 (95%CI 5.66-11.20), compared to AUROC NEWS2 in sepsis 0.962 (95%CI 5.54-7.51) or in septic shock 0.974 (95%CI 6.11-9.74). MEDS, a specific designed score was superior to NEWS2PSP in predicting mortality AUROC MEDS 0.762 (95%CI 2.55-6.01), AUROC NEWS2PSP 0.656 (95%CI 1.21-5.39).

Another compounded score was tested: for PSP<200 pg/ml we have given 1 point, 2 points for PSP=200- 300 pg/ml, 3 points for PSP=300-500 pg/ml, 4 points for PSP=500-1000 pg/ml and 5 points for PSP>1000 pg/ml. Those values were added to NEWS2 and formed NEWS2PSP2 which has no more added value to NEWS2 for predicting sepsis (AUROC NEWS2 0.962 (95%CI 5.54-7.51), AUROC NEWS2PSP2 0.953 (95%CI 5.69-7.84), minimal in septic shock (AUROC NEWS2 0.974 (95%CI 6.11-9.74), AUROC NEWS2PSP2 0.975 (95%CI 6.31-10.19). MEDS kept an advantage in predicting death over NEWS2PSP2 (AUROC MEDS 0.762 (95%CI 2.55-6.01), AUROC NEWS2PSP2 0.676 (95%CI 0.94-4.17).

NEWS2PSP3 resulted from granting 1 point if PSP>1000 and 0 points if PSP<1000- with no better prognostic value over NEWS2 for predicting sepsis ((AUROC NEWS2 0.962 (95%CI 5.54-7.51), AUROC NEWS2PSP3 0.956 (95%CI 5.95-7.65) and kept a slightly advantage over NEWS2 in septic shock AUROC NEWS2 0.974 (95%CI 6.11-9.74), AUROC NEWS2PSP3 0.975 (95%CI 6.22-9.96). MEDS kept an advantage in predicting death over NEWS2PSP3 (AUROC MEDS 0.762 (95%CI 2.55-6.01), AUROC NEWS2PSP3 0.672 (95%CI 0.90-4.03).

Granting 0 points for PSP<5000 pg/ml, 1 point for PSP=5000-10000 pg/ml and 2 points for PSP>10000 and adding these points to NEWS2 lead us to NEWS2PSP4 which is superior to NEWS2 (AUROC NEWS2PSP4 0.971 (95%CI 5.69-7.65) compared to AUROC NEWS2 0.962 (95%CI 5.54-7.51). Using a cut-off value of 9.5 for NEWS2PSP4 we can diagnosis of sepsis with a sensitivity of 60%. (for a NEWS2PSP4 compound score >6.5 sepsis is diagnosed with a sensitivity of 90% and 90.5% specificity).

Using this simple algorithm, for 16 patients the NEWS2 score had changed (12.8%). For 10 out of 95 (10.52%) without sepsis and 6 out of 30 (20%) of septic patients, more points were added to NEWS2 meaning that more septic patients were diagnosed before an infection become life-threatening.

For septic shock NEWS2PSP4 was a reliable score; AUROC values were as follows: AUROC NEWS2 0.974 (95%CI 6.11-9.74), and NEWS2PSP4 0.972 (95%CI 6.07-9.76) (very close), while MEDS kept the advantage in predicting mortality (similar AUROC for NEWS2 and NEWS2PSP4) (AUROC NEWS2 0.670 (95%CI 0.79-3.85), MEDS 0.762 (95%CI 2.55-6.01), NEWS2PSP4 0.670 (95%CI 0.82-3.91). Figures 1, 2 and 3 represent receiver-operating characteristics (ROC) curves for NEWS2, MEDS, PSP and the derived scores for sepsis/ septic shock/mortality as above.

DISCUSSION

In our study we proved that adding a specific biomarker, presepsin, to NEWS2 we can put a sepsis diagnosis earlier, reliable, with increased accuracy, avoiding further deterioration. Studies have proved that clinical deterioration is often forecasted by changes in vital signs up to 6 to 24 hours [20, 21]. This can buy time for a specific patient, but in fact also for the system to recover.

To be remembered, although an increased specificity sign, ST elevation, did not decrease mortality per se. Only after angina pectoris was combined with a specific biomarker, troponin, combined with proactive actions, coronary stenting, markedly decreased the mortality.

Immunity against a microorganism relies primarily on the activity of monocytes, macrophages and granulocytes that recognize pathogen-associated molecular patterns that activate downstream pathways and participate to bacteria clearance. This is partly done through a cluster-of-differentiation marker protein 14 (CD14), which has an immediate response against lipopolysaccharides (LPS) [14, 22]. After binding of LPS to CD14 through the LPS-binding protein (LBP), a subtype of soluble CD14 (sCD14-ST, or presepsin, a 13 kDa protein that is a truncated N-terminal fragment of CD14 [15, 16] is released to the blood flow.

Different scores were used as specific tools in specific circumstances. The more versatile ones are the ones that can be used in as many as possible situations, with minimum of resources, as fast as possible. National Early Warning Score 2 (NEWS2) is released after 5 years of trials after the first version of evaluation in hospitals in UK. This score advocates a system to standardize the assessment and response to acute illness and its efficacy was proven in time. Using six simple physiological parameters already recorded in routine practice, NEWS2 is a pragmatic approach with a key emphasis on system-wide standardization

Rapid diagnostic on ED saves lives. Acute myocardial infarction, stroke and sepsis are medical conditions when short time to diagnosis is of paramount importance, that cannot be overemphasized.

NEWS2 can be used as a point of departure for assessing an acute medical illness, but to accurately diagnose a patient a specific tool is needed (ST elevation for acute myocardial infarction on EKG, CT scan for stroke and nowadays qSOFA criteria for sepsis).

As Sepsis-3 stated, a sepsis is declared when an infection becomes life-threatening. This puts a rapid diagnose with minimal resources. Having some preliminary results can gain time to earlier diagnose a life-threatening condition and to prevent further deterioration. When we have the Sepsis-3 criteria, the diagnosis is obvious.

We proved that with minimal resources, monitoring vital parameters and assessing a score and when suitable a POCT biomarker, in 15 minutes we raised the suspicion of sepsis, before becoming manifest, with increased accuracy, gaining at least 45 minutes. We found that a biomarker, presepsin, can accurately earlier diagnose sepsis used in correlation with a verified score, NEWS2 which is used for a patient to access the appropriate level of care at a certain moment. We also took into account MEDS as a level of reference, for its power to predict the prognosis due to sepsis (Mortality in Emergency Department Score).

Of note is that the presepsin values were used to help diagnose sepsis after Sepsis-2 definition, but in our study, we tried to use the presepsin for earlier detection of sepsis, after Sepsis-3 definition, before the clinical life-threatening criteria to become manifest (SBP≤100 mmHg, ≥22 breaths per min, GCS<15).

With an altered mental state, incomplete anamnesis to be taken from relatives or the lack of proper documents, increasing number of patients on admission and too often not enough personnel, an accurate, proper assessment on admission is mandatory. After the initial evaluation, vital functions monitoring and blood samples are taken, before more complete laboratory analysis to be available – with a median of one hour, the Point-Of-Care-Testing devices can give you a more comprehensive understanding of the actual medical state in approximatively 15 minutes. POCT biomarkers, arterial gases analysis and complete blood count with multiple scores applied, offer a more comprehensive assessment of a patient and sometimes prioritize the subsequent investigations. While a MEDS score needs not so easy to get information (rapid terminal comorbid illness, neutrophil bands, lower respiratory infection or nursing home resident) NEWS2 is a reliable, verified score intended to be used for monitoring, with increased sensitivity. Based on initial evaluation, taking presepsin (available in 17 minutes) only to patients with SIRS and NEWS2 assessment, taken together increased the number of the patients to be earlier diagnosed with sepsis with 10%. Presepsin was the ideal biomarker due to the fact that it has earlier response compared with procalcitonin after the onset of an infection (peak level<2 h) plus a short half-time (0,5-1 h) compared with those of procalcitonin (2-3 h and 20-24 h, respectively) and CRP (6 h and 4-6 h, respectively) lead us to use this biomarker. The lack of specificity as procalcitonin increases also in surgical interventions, cardiogenic shock, thermal shock, graft-versus-host disease, immunotherapy, burns, acute pancreatitis lead us to consider using presepsin as specific biomarker [21, 23, 24].

To our knowledge this was the first report of PSP and NEWS2 score used in combination for sepsis diagnosis. Nevertheless, although this association is better for earlier detection of sepsis, there no added advantages in predicting septic shock or mortality.

Sepsis is not a completely understood pathology. Surviving Sepsis Campaign with the periodic reevaluation (even the Sepsis, Sepsis-2, Sepsis-3 definition suggests the dynamics and the major concern involved) still leaves room for refinement and improvement. Our study reflects our approach for earlier diagnose of sepsis. Having a patient with clear criteria for sepsis accordingly to qSOFA leaves no room for doubts and the nowadays guidelines stress the importance of earlier diagnosis and rapid measurements to be taken (2018 Sepsis Uptated) in the first hour.

Sepsis defined as life-threatening organ dysfunction caused by a dysregulated host response to infection does not shed light over the dysregulation. Is it due to the increased aggressivity of the pathogen, to the amount of the pathogen, to the particularities of the injured organ/system, of the comorbidities which decrease the defense mechanisms, of the defense of the defense mechanisms itself? In order to achieve timely treatment for a possible lethal condition, a sensitive screening tool is more important than a specific one [25, 26] and identifying the poor prognostic factors may have a role [27].

Although qSOFA has an increased specificity and minimal resources to be used, lacks the sensibility and consequently the diagnosis of sepsis is often put too late. Even one point granted on initial evaluation does not imply that subsequent evolution is not going to be worse, to further deteriorate without becoming life-threatening. So, more refined approach is sometimes necessary.

Study limitations and strengths.

The present study has some limitation. First, being a single center retrospective, observational study we may not have a comprehensive view of this complex pathology. Second, being a tertiary hospital, may have had more complex patients which may have biased in generalizing the conclusions. Future studies should include more patients from different sites. Third, sepsis defined as life-threatening condition, may alter the health status by itself- an out-control infection might bias the renal function by itself or by aggravation of an already altered renal function as a comorbidity in a more general health status. Fourth, the limited number of patients studied, although significant, are a mere part of the patients with sepsis, so the drawn conclusions should be further verified. Fifth, the size of the cohort might have not enough power requested to draw final conclusions. Finally, although already described in literature, the correlation between presepsin/ biomarker with renal clearance levels and kidney function in patients with life-threatening condition should be studied further.

As strengths in our study we assessed the impact of an earlier intervention over a life-threatening condition in which time is of critical importance. Although widely used, the scores are sometimes inadequately applied. Making distinction between the goals and the moment to be applied to, a score is not a goal in itself. Using a monitoring, verified score as NEWS2, high sensitivity, low specificity combined with a specific biomarker with short time until peak values are attained, lead us to suggest that before becoming dysregulated and life threatening, the sepsis might have an earlier, more optimized approach.

CONCLUSIONS

In the present study, we have tried to assess the impact of a monitoring score and a rapid POCT biomarker, in a condition where time is of critical importance. We acknowledged that in a not completely understood lethal pathology as sepsis, different approaches might be tried in order to earlier detect a life-threatening condition. Using a verified monitoring score, NEWS2, with increased sensibility and low specificity and presepsin, POCT biomarker result within 17 minutes, we diagnosed sepsis earlier.

Guidelines for authors

Thank you for your interest in the *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully before submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review.

Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission following the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

We look forward to your submission.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians and Pharmacists. The Journal publishes peer-reviewed original papers, reviews, meta-analyses, and systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine.

Papers cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and historical aspects of the subject areas.

Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor will not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer-reviewed under the direction of an Editor. The Editor reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form, and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed following the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013) (http://www.wma.net/en/30publications/10policies/b3/index.html).

It should also state clearly in the text that all persons gave their informed consent before their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects from being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

(1) Accessible to the public at no charge;
(2) Searchable by standard, electronic (Internet-based) methods;
(3) Open to all prospective registrants free of charge or at minimal cost;
(4) Validates registered information;
(5) Identifies trials with a unique number; and
(6) includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of the last follow-up, the target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, except for Editorials, must contain an abstract of no more than 250 words. Abstracts for original articles should be formatted into subheadings, as detailed below. Titles must not be longer than 120 characters (including spaces).

Editorials

These are invited by the Editor-in-Chief or their delegated editor and should be a brief review of the subject concerned, regarding and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure, and cite up to 15 references, including the source article [this should be cited as Rom J Mil Med (year); (vol): [this issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine and advances in clinical practice. Most published reviews are in response to the editorial invitation, including thematically related “mini-series” of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are limited to 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes the submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for the preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer-review process. Meta-Analyses and Systematic Reviews have a word limit of 3500–5000 words, with an abstract of up to 250 words and up to 75 references, and 3–7 figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and/or historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Original articles are limited to 3000 words, with an abstract of up to 250 words and up to 50 references, and 3–7 figures and tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Education and Imaging Coordinating Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features, and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as 'What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?' Part 2 will briefly describe the imaging features, particularly those that lead to a diagnosis or which are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, the presentation of analogous cases or related images from a similar case might be appropriate. Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background to and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors' revised 'Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication, as presented at http://www.ICMJE.org/.

Spelling. The journal uses US spelling and authors should, therefore, follow the latest edition of the Merriam-Webster's Collegiate Dictionary.

Units. All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations should be used sparingly and only where they ease the reader's task by reducing the repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: title page; main text file; figures.

Title page

The title page should contain (i) a short informative title that contains the major keywords. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgments. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors' industrial links and affiliations. In the case of clinical trials or any article describing the use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer-reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented in the following order: (i) abstract and keywords, (ii) text, (iii) references, (iv) tables (each table complete with title and footnotes), (vii) figure legends. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as a parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 250 words or less the purpose, basic procedures, main findings, and principal conclusions of the study. Divide the abstract with the headings: *Background and Aim, Methods, Results, Conclusions*. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to five keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine's Medical Subject Headings (MeSH) browser—(http://www.nlm.nih.gov/mesh/meshhome.html).

Text

Authors should use subheadings to divide the sections of their manuscript: *Introduction, Methods, Results, Discussion Acknowledgments, and References*.

References

The Vancouver system of referencing should be used. In the text, references should be cited using Arabic numerals in square brackets in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or fewer; when seven or more list the first three followed by et al. Names of journals should be abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

References should be listed in the following form:

Number references in the order cited as Arabic numerals in square brackets on the line. Only literature that is published or in press (with the name of the publication known) may be numbered and listed; abstracts and letters to the editor may be cited, but they must be less than 3 years old and identified as such. Refer to only in the text, in parentheses, other material (manuscripts submitted, unpublished data, personal communications, and the like) as in the following example: (Chercheur X, unpublished data). If the owner of the unpublished data or personal communication is not an author of the manuscript under review, a signed statement is required verifying the accuracy of the attributed information and agreement to its publication. Use Index Medicus as the style guide for references and other journal abbreviations. List all authors up to six, using six and "et al." when the number is greater than six.

Tables

Tables should be self-contained and complement, but not duplicate, the information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table, legend, and footnotes must be understandable without reference to the text. Vertical lines should not be used to separate columns. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, §, ¶ should be used (in that order), and *, **, *** should be reserved for *P*-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication: Although low-quality images are adequate for review purposes, publication requires high-quality images to prevent the final product from being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at rjmilmed@yahoo.com

A cover letter containing an authorship statement should be included.

The cover letter should include a statement covering each of the following areas:

1. Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author.
2. Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.
3. A statement outlining how ethical clearance has been obtained for the research, particularly concerning studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research must comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.
4. For research involving pharmacological agents, devices, or medical

technology, a clear Conflict of Interest statement concerning any funding from or pecuniary interests in companies could be perceived as a potential conflict of interest in the outcome of the research.

5. For clinical trials, these have been registered in a publically accessible database.

If the above items are not included in the cover letter, manuscripts cannot be sent for review.

Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word files need to be included upon submission: A title page file and the main text file that includes all parts of the text in the sequence indicated in the section 'Parts of the manuscript', including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using Microsoft Word, double-spaced. The top, bottom, and side margins should be 30 mm. All pages should be numbered consecutively in the top right-hand corner, beginning with the first page of the main text file.

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, low-resolution figures saved as .jpg or .bmp files should be uploaded, for ease of transmission during the review process. Upon acceptance of the article, high-resolution figures (at least 300 d.p.i.) saved as .eps or .tif files will be required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted papers will be passed to the production team for publication. The author identified as the formal corresponding author for the paper will receive an email, being asked to complete an electronic license agreement on behalf of all authors on the paper.

Accepted Articles

The accepted ‘in press’ manuscripts are published online very soon after acceptance, before copy-editing or typesetting. Accepted Articles are published online a few days after final acceptance, appear in PDF format only, are given a Digital Object Identifier (DOI), which allows them to be cited and tracked. After print publication, the DOI remains valid and can continue to be used to cite and access the article. Given that copyright licensing is a condition of publication, a completed copyright form is required before a manuscript can be processed as an Accepted Article.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing instructions on how to provide proof corrections to the article. It is therefore essential that a working e-mail address is provided for the corresponding author. Proofs should be corrected carefully; the responsibility for detecting errors lies with the author. The proof should be checked, and approval to publish the article should be emailed to the Publisher by the date indicated; otherwise, it may be signed off on by the Editor or held over to the next issue.

COPYRIGHT, LICENSING, AND ONLINE OPEN

Details are on the Copyright Agreement Form that must be completed and signed when the Article is accepted.

Guidelines for authors

Thank you for your interest in *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully prior to submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review.

Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission in accordance with the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

We look forward to your submission.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians and Pharmacists. The Journal publishes peer-reviewed original papers, reviews, meta-analyses and systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine.

Papers cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and historical aspects of the subject areas.

Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor will not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer reviewed under the direction of an Editor. The Editor reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed in accordance with the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013), available at http://www.wma.net/en/30publications/10policies/b3/index.html. It should also state clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

(1) Accessible to the public at no charge;

(2) Searchable by standard, electronic (Internet-based) methods;

(3) Open to all prospective registrants free of charge or at minimal cost;

(4) Validates registered information;

(5) Identifies trials with a unique number; and

(6) includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of last follow-up, target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that

your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, with the exception of Editorials, must contain an abstract of no more than 250 words. Abstracts for original articles should be formatted into subheadings, as detailed below. Titles must not be longer than 120 characters (including spaces).

Editorials

These are invited by the Editor-in-Chief or their delegated editor, and should be a brief review of the subject concerned, with reference to and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure and cite up to 15 references, including the source article [this should be cited as Military Med. Today (year); (vol): [this issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine, and advances in clinical practice. Most published reviews are in response to editorial invitation, including thematically related “mini-series” of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are limited to 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer review process. Meta-Analyses and Systematic Reviews have a word limit of 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and/or historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Original articles are limited to 3000 words, with an abstract of up to 250 words and up to 50 references and 3–7 figures and tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Education and Imaging Coordinating Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as ‘What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?’ Part 2 will briefly describe the imaging features, particularly those that lead to diagnosis or which are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, presentation of analogous cases or related images from a similar case might be appropriate. Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background to and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors’ revised ‘Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication’, as presented at http://www.ICMJE.org/.

Spelling. The journal uses US spelling and authors should therefore follow the latest edition of the Merriam-Webster’s Collegiate Dictionary.

Units. All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations should be used sparingly and only where they ease the reader’s task by reducing repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: title page; main text file; figures.

Title page

The title page should contain (i) a short informative title that contains the major key words. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi)

acknowledgements. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors' industrial links and affiliations. In the case of clinical trials or any article describing use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented in the following order: (i) abstract and key words, (ii) text, (iii) references, (iv) tables (each table complete with title and footnotes), (vii) figure legends. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 250 words or less the purpose, basic procedures, main findings and principal conclusions of the study. Divide the abstract with the headings: *Background and Aim, Methods, Results, Conclusions*. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to five keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine's Medical Subject Headings (MeSH) browser—(http://www.nlm.nih.gov/mesh/meshhome.html).

Text

Authors should use subheadings to divide the sections of their manuscript: *Introduction, Methods, Results, Discussion Acknowledgments and References*.

References

The Vancouver system of referencing should be used. In the text, references should be cited using superscript Arabic numerals in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or less; when seven or more list the first three followed by et al. Names of journals should be abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

References should be listed in the following form:

Number references in the order cited as Arabic numerals in parentheses on the line. Only literature that is published or in press (with the name of the publication known) may be numbered and listed; abstracts and letters to the editor may be cited, but they must be less than 3 years old and identified as such. Refer to only in the text, in parentheses, other material (manuscripts submitted, unpublished data, personal communications, and the like) as in the following example: (Chercheur X, unpublished data). If the owner of the unpublished data or personal communication is not an author of the manuscript under review, a signed statement is required verifying the accuracy of the attributed information and agreement to its publication. Use Index Medicus as the style guide for references and other journal abbreviations. List all authors up to six, using six and "et al." when the number is greater than six.

Tables

Tables should be self-contained and complement, but not duplicate, information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table, legend and footnotes must be understandable without reference to the text. Vertical lines should not be used to separate columns. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, §, ¶ should be used (in that order) and *, **, *** should be reserved for *P*-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication: Although low quality images are adequate for review purposes, publication requires high quality images to prevent the final product being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at rjmilmed@yahoo.com

A cover letter containing an authorship statement should be included.

The cover letter should include a statement covering each of the following areas:

1. Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author.
2. Confirmation that the manuscript has not been published

previously, in any language, in whole or in part, and is not currently under consideration elsewhere.

3. A statement outlining how ethical clearance has been obtained for the research, particularly in relation to studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research must comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.

4. For research involving pharmacological agents, devices or medical technology, a clear Conflict of Interest statement in relation to any funding from or pecuniary interests in companies that could be perceived as a potential conflict of interest in the outcome of the research.

5. For clinical trials, that these have been registered in a publically accessible database.

If the above items are not included in the cover letter, manuscripts cannot be sent for review.

Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word-files need to be included upon submission: A title page file and a main text file that includes all parts of the text in the sequence indicated in the section 'Parts of the manuscript', including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using Microsoft Word, doubled-spaced. The top, bottom and side margins should be 30 mm. All pages should be numbered consecutively in the top right-hand corner, beginning with the first page of the main text file.

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, low-resolution figures saved as .jpg or .bmp files should be uploaded, for ease of transmission during the review process. Upon acceptance of the article, high-resolution figures (at least 300 d.p.i.) saved as .eps or .tif files will be required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted papers will be passed to production team for publication. The author identified as the formal corresponding author for the paper will receive an email, being asked to complete an electronic license agreement on behalf of all authors on the paper.

Accepted Articles

The accepted 'in press' manuscripts are published online very soon after acceptance, prior to copy-editing or typesetting. Accepted Articles are published online a few days after final acceptance, appear in PDF format only, are given a Digital Object Identifier (DOI), which allows them to be cited and tracked. After print publication, the DOI remains valid and can continue to be used to cite and access the article. Given that copyright licensing is a condition of publication, a completed copyright form is required before a manuscript can be processed as an Accepted Article.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing instructions on how to provide proof corrections to the article. It is therefore essential that a working e-mail address is provided for the corresponding author. Proofs should be corrected carefully; the responsibility for detecting errors lies with the author. The proof should be checked, and approval to publish the article should be emailed to the Publisher by the date indicated; otherwise, it may be signed off on by the Editor or held over to the next issue.

Offprint

A PDF reprint of the article will be supplied free of charge to the corresponding author. Additional printed offprint may be ordered for a fee.

COPYRIGHT, LICENSING AND ONLINE OPEN

Details are on the Copyright Agreement Form that must be completed and signed when the Article is accepted.

ADMINISTRATIVE ISSUES

Guidelines for authors

Thank you for your interest in the *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully before submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review.

Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission following the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

We look forward to your submission.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians and Pharmacists. The Journal publishes peer-reviewed original papers, reviews, meta-analyses, and systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine.

Papers cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and historical aspects of the subject areas.

Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor will not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer-reviewed under the direction of an Editor. The Editor reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form, and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed following the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013) (http://www.wma.net/en/30publications/10policies/b3/index.html).

It should also state clearly in the text that all persons gave their informed consent before their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects from being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

(1) Accessible to the public at no charge;
(2) Searchable by standard, electronic (Internet-based) methods;
(3) Open to all prospective registrants free of charge or at minimal cost;
(4) Validates registered information;
(5) Identifies trials with a unique number; and
(6) includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of the last follow-up, the target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, except for Editorials, must contain an abstract of no more than 250 words. Abstracts for original articles should be formatted into subheadings, as detailed below. Titles must not be longer than 120 characters (including spaces).

Editorials

These are invited by the Editor-in-Chief or their delegated editor and should be a brief review of the subject concerned, regarding and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure, and cite up to 15 references, including the source article [this should be cited as Rom J Mil Med (year); (vol): [this issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine and advances in clinical practice. Most published reviews are in response to the editorial invitation, including thematically related "mini-series" of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are limited to 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes the submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for the preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer-review process. Meta-Analyses and Systematic Reviews have a word limit of 3500–5000 words, with an abstract of up to 250 words and up to 75 references, and 3–7 figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and/or historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Original articles are limited to 3000 words, with an abstract of up to 250 words and up to 50 references, and 3–7 figures and tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Education and Imaging Coordinating Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features, and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as ‘What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?’ Part 2 will briefly describe the imaging features, particularly those that lead to a diagnosis or which are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, the presentation of analogous cases or related images from a similar case might be appropriate. Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background to and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors’ revised ‘Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication, as presented at http://www.ICMJE.org/.

Spelling. The journal uses US spelling and authors should, therefore, follow the latest edition of the Merriam-Webster’s Collegiate Dictionary.

Units. All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations should be used sparingly and only where they ease the reader’s task by reducing the repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: title page; main text file; figures.

Title page

The title page should contain (i) a short informative title that contains the major keywords. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgments. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors’ industrial links and affiliations. In the case of clinical trials or any article describing the use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer-reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented in the following order: (i) abstract and keywords, (ii) text, (iii) references, (iv) tables (each table complete with title and footnotes), (vii) figure legends. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as a parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 250 words or less the purpose, basic procedures, main findings, and principal conclusions of the study. Divide the abstract with the headings: *Background and Aim, Methods, Results, Conclusions*. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to five keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine’s Medical Subject Headings (MeSH) browser—(http://www.nlm.nih.gov/mesh/meshhome.html).

Text

Authors should use subheadings to divide the sections of their manuscript: *Introduction, Methods, Results, Discussion Acknowledgments, and References*.

References

The Vancouver system of referencing should be used. In the text, references should be cited using Arabic numerals in square brackets in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or fewer; when seven or more list the first three followed by et al. Names of journals should be abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

References should be listed in the following form:

Number references in the order cited as Arabic numerals in square brackets on the line. Only literature that is published or in press (with the name of the publication known) may be numbered and listed; abstracts and letters to the editor may be cited, but they must be less than 3 years old and identified as such. Refer to only in the text, in parentheses, other material (manuscripts submitted, unpublished data, personal communications, and the like) as in the following example: (Chercheur X, unpublished data). If the owner of the unpublished data or personal communication is not an author of the manuscript under review, a signed statement is required verifying the accuracy of the attributed information and agreement to its publication. Use Index Medicus as the style guide for references and other journal abbreviations. List all authors up to six, using six and "et al." when the number is greater than six.

Tables

Tables should be self-contained and complement, but not duplicate, the information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table, legend, and footnotes must be understandable without reference to the text. Vertical lines should not be used to separate columns. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, §, ¶ should be used (in that order), and *, **, *** should be reserved for *P*-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication: Although low-quality images are adequate for review purposes, publication requires high-quality images to prevent the final product from being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at rjmilmed@yahoo.com

A cover letter containing an authorship statement should be included.

The cover letter should include a statement covering each of the following areas:

1. Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author.
2. Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.
3. A statement outlining how ethical clearance has been obtained for the research, particularly concerning studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research must comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.
4. For research involving pharmacological agents, devices, or medical technology, a clear Conflict of Interest statement concerning any funding from or pecuniary interests in companies could be perceived as a potential conflict of interest in the outcome of the research.
5. For clinical trials, these have been registered in a publically accessible database.

If the above items are not included in the cover letter, manuscripts cannot be sent for review.

Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word files need to be included upon submission: A title page file and the main text file that includes all parts of the text in the sequence indicated in the section 'Parts of the manuscript', including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using Microsoft Word, double-spaced. The top, bottom, and side margins should be 30 mm. All pages should be numbered consecutively in the top right-hand corner, beginning with the first page of the main text file.

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, low-resolution figures saved as .jpg or .bmp files should be uploaded, for ease of transmission during the review process. Upon acceptance of the article, high-resolution figures (at least 300 d.p.i.) saved as .eps or .tif files will be required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted papers will be passed to the production team for publication. The author identified as the formal corresponding author for the paper will receive an email, being asked to complete an electronic license agreement on behalf of all authors on the paper.

Accepted Articles

The accepted ‘in press’ manuscripts are published online very soon after acceptance, before copy-editing or typesetting. Accepted Articles are published online a few days after final acceptance, appear in PDF format only, are given a Digital Object Identifier (DOI), which allows them to be cited and tracked. After print publication, the DOI remains valid and can continue to be used to cite and access the article. Given that copyright licensing is a condition of publication, a completed copyright form is required before a manuscript can be processed as an Accepted Article.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing instructions on how to provide proof corrections to the article. It is therefore essential that a working e-mail address is provided for the corresponding author. Proofs should be corrected carefully; the responsibility for detecting errors lies with the author. The proof should be checked, and approval to publish the article should be emailed to the Publisher by the date indicated; otherwise, it may be signed off on by the Editor or held over to the next issue.

COPYRIGHT, LICENSING, AND ONLINE OPEN

Details are on the Copyright Agreement Form that must be completed and signed when the Article is accepted.

Guidelines for authors

Thank you for your interest in the *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully before submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review.

Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission following the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

We look forward to your submission.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians and Pharmacists. The Journal publishes peer-reviewed original papers, reviews, meta-analyses, and systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine.

Papers cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and historical aspects of the subject areas.

Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor will not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer-reviewed under the direction of an Editor. The Editor reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form, and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed following the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013) (http://www.wma.net/en/30publications/10policies/b3/index.html).

It should also state clearly in the text that all persons gave their informed consent before their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects from being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

(1) Accessible to the public at no charge;
(2) Searchable by standard, electronic (Internet-based) methods;
(3) Open to all prospective registrants free of charge or at minimal cost;
(4) Validates registered information;
(5) Identifies trials with a unique number; and
(6) includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of the last follow-up, the target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, except for Editorials, must contain an abstract of no more than 250 words. Abstracts for original articles should be formatted into subheadings, as detailed below. Titles must not be longer than 120 characters (including spaces).

Editorials

These are invited by the Editor-in-Chief or their delegated editor and should be a brief review of the subject concerned, regarding and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure, and cite up to 15 references, including the source article [this should be cited as Rom J Mil Med (year); (vol): [this issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine and advances in clinical practice. Most published reviews are in response to the editorial invitation, including thematically related “mini-series” of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are limited to 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes the submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for the preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer-review process. Meta-Analyses and Systematic Reviews have a word limit of 3500–5000 words, with an abstract of up to 250 words and up to 75 references, and 3–7 figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and/or historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Original articles are limited to 3000 words, with an abstract of up to 250 words and up to 50 references, and 3–7 figures and tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Education and Imaging Coordinating Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features, and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as 'What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?' Part 2 will briefly describe the imaging features, particularly those that lead to a diagnosis or which are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, the presentation of analogous cases or related images from a similar case might be appropriate. Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background to and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors' revised 'Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication, as presented at http://www.ICMJE.org/.

Spelling. The journal uses US spelling and authors should, therefore, follow the latest edition of the Merriam-Webster's Collegiate Dictionary.

Units. All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations should be used sparingly and only where they ease the reader's task by reducing the repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: title page; main text file; figures.

Title page

The title page should contain (i) a short informative title that contains the major keywords. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgments. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors' industrial links and affiliations. In the case of clinical trials or any article describing the use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer-reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented in the following order: (i) abstract and keywords, (ii) text, (iii) references, (iv) tables (each table complete with title and footnotes), (vii) figure legends. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as a parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 250 words or less the purpose, basic procedures, main findings, and principal conclusions of the study. Divide the abstract with the headings: *Background and Aim, Methods, Results, Conclusions*. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to five keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine's Medical Subject Headings (MeSH) browser—(http://www.nlm.nih.gov/mesh/meshhome.html).

Text

Authors should use subheadings to divide the sections of their manuscript: *Introduction, Methods, Results, Discussion Acknowledgments, and References*.

References

The Vancouver system of referencing should be used. In the text, references should be cited using Arabic numerals in square brackets in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or fewer; when seven or more list the first three followed by et al. Names of journals should be abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

References should be listed in the following form:

Number references in the order cited as Arabic numerals in square brackets on the line. Only literature that is published or in press (with the name of the publication known) may be numbered and listed; abstracts and letters to the editor may be cited, but they must be less than 3 years old and identified as such. Refer to only in the text, in parentheses, other material (manuscripts submitted, unpublished data, personal communications, and the like) as in the following example: (Chercheur X, unpublished data). If the owner of the unpublished data or personal communication is not an author of the manuscript under review, a signed statement is required verifying the accuracy of the attributed information and agreement to its publication. Use Index Medicus as the style guide for references and other journal abbreviations. List all authors up to six, using six and "et al." when the number is greater than six.

Tables

Tables should be self-contained and complement, but not duplicate, the information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table, legend, and footnotes must be understandable without reference to the text. Footnote symbols: †, ‡, §, ¶ should be used (in that order), and *, **, *** should be reserved for *P*-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication: Although low-quality images are adequate for review purposes, publication requires high-quality images to prevent the final product from being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at rjmilmed@yahoo.com

A cover letter containing an authorship statement should be included.

The cover letter should include a statement covering each of the following areas:

1. Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author.
2. Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.
3. A statement outlining how ethical clearance has been obtained for the research, particularly concerning studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research must comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.
4. For research involving pharmacological agents, devices, or medical

technology, a clear Conflict of Interest statement concerning any funding from or pecuniary interests in companies could be perceived as a potential conflict of interest in the outcome of the research.

5. For clinical trials, these have been registered in a publically accessible database.

If the above items are not included in the cover letter, manuscripts cannot be sent for review.

Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word files need to be included upon submission: A title page file and the main text file that includes all parts of the text in the sequence indicated in the section 'Parts of the manuscript', including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using Microsoft Word, double-spaced. The top, bottom, and side margins should be 30 mm. All pages should be numbered consecutively in the top right-hand corner, beginning with the first page of the main text file.

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, low-resolution figures saved as .jpg or .bmp files should be uploaded, for ease of transmission during the review process. Upon acceptance of the article, high-resolution figures (at least 300 d.p.i.) saved as .eps or .tif files will be required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted papers will be passed to the production team for publication. The author identified as the formal corresponding author for the paper will receive an email, being asked to complete an electronic license agreement on behalf of all authors on the paper.

Accepted Articles

The accepted ‘in press’ manuscripts are published online very soon after acceptance, before copy-editing or typesetting. Accepted Articles are published online a few days after final acceptance, appear in PDF format only, are given a Digital Object Identifier (DOI), which allows them to be cited and tracked. After print publication, the DOI remains valid and can continue to be used to cite and access the article. Given that copyright licensing is a condition of publication, a completed copyright form is required before a manuscript can be processed as an Accepted Article.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing instructions on how to provide proof corrections to the article. It is therefore essential that a working e-mail address is provided for the corresponding author. Proofs should be corrected carefully; the responsibility for detecting errors lies with the author. The proof should be checked, and approval to publish the article should be emailed to the Publisher by the date indicated; otherwise, it may be signed off on by the Editor or held over to the next issue.

COPYRIGHT, LICENSING, AND ONLINE OPEN

Details are on the Copyright Agreement Form that must be completed and signed when the Article is accepted.

Guidelines for authors

Thank you for your interest in the *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully before submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review.

Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission following the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

We look forward to your submission.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians and Pharmacists. The Journal publishes peer-reviewed original papers, reviews, meta-analyses, and systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine.

Papers cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and historical aspects of the subject areas.

Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor will not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer-reviewed under the direction of an Editor. The Editor reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form, and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed following the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013) (http://www.wma.net/en/30publications/10policies/b3/index.html).

It should also state clearly in the text that all persons gave their informed consent before their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects from being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

(1) Accessible to the public at no charge;
(2) Searchable by standard, electronic (Internet-based) methods;
(3) Open to all prospective registrants free of charge or at minimal cost;
(4) Validates registered information;
(5) Identifies trials with a unique number; and
(6) includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of the last follow-up, the target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, except for Editorials, must contain an abstract of no more than 250 words. Abstracts for original articles should be formatted into subheadings, as detailed below. Titles must not be longer than 120 characters (including spaces).

Editorials

These are invited by the Editor-in-Chief or their delegated editor and should be a brief review of the subject concerned, regarding and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure, and cite up to 15 references, including the source article [this should be cited as Rom J Mil Med (year); (vol): [this issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine and advances in clinical practice. Most published reviews are in response to the editorial invitation, including thematically related “mini-series” of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are limited to 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes the submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for the preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer-review process. Meta-Analyses and Systematic Reviews have a word limit of 3500–5000 words, with an abstract of up to 250 words and up to 75 references, and 3–7 figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and/or historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Original articles are limited to 3000 words, with an abstract of up to 250 words and up to 50 references, and 3–7 figures and tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Education and Imaging Coordinating Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features, and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as 'What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?' Part 2 will briefly describe the imaging features, particularly those that lead to a diagnosis or which are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, the presentation of analogous cases or related images from a similar case might be appropriate. Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background to and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors' revised 'Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication, as presented at http://www.ICMJE.org/.

Spelling. The journal uses US spelling and authors should, therefore, follow the latest edition of the Merriam-Webster's Collegiate Dictionary.

Units. All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations should be used sparingly and only where they ease the reader's task by reducing the repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: title page; main text file; figures.

Title page

The title page should contain (i) a short informative title that contains the major keywords. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgments. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors' industrial links and affiliations. In the case of clinical trials or any article describing the use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer-reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented in the following order: (i) abstract and keywords, (ii) text, (iii) references, (iv) tables (each table complete with title and footnotes), (vii) figure legends. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as a parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 250 words or less the purpose, basic procedures, main findings, and principal conclusions of the study. Divide the abstract with the headings: *Background and Aim, Methods, Results, Conclusions*. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to five keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine's Medical Subject Headings (MeSH) browser—(http://www.nlm.nih.gov/mesh/meshhome.html).

Text

Authors should use subheadings to divide the sections of their manuscript: *Introduction, Methods, Results, Discussion Acknowledgments, and References*.

References

The Vancouver system of referencing should be used. In the text, references should be cited using Arabic numerals in square brackets in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or fewer; when seven or more list the first three followed by et al. Names of journals should be abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

References should be listed in the following form:

Number references in the order cited as Arabic numerals in square brackets on the line. Only literature that is published or in press (with the name of the publication known) may be numbered and listed; abstracts and letters to the editor may be cited, but they must be less than 3 years old and identified as such. Refer to only in the text, in parentheses, other material (manuscripts submitted, unpublished data, personal communications, and the like) as in the following example: (Chercheur X, unpublished data). If the owner of the unpublished data or personal communication is not an author of the manuscript under review, a signed statement is required verifying the accuracy of the attributed information and agreement to its publication. Use Index Medicus as the style guide for references and other journal abbreviations. List all authors up to six, using six and "et al." when the number is greater than six.

Tables

Tables should be self-contained and complement, but not duplicate, the information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table, legend, and footnotes must be understandable without reference to the text. Vertical lines should not be used to separate columns. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, §, ¶ should be used (in that order), and *, **, *** should be reserved for *P*-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication: Although low-quality images are adequate for review purposes, publication requires high-quality images to prevent the final product from being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at rjmilmed@yahoo.com

A cover letter containing an authorship statement should be included.

The cover letter should include a statement covering each of the following areas:

1. Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author.
2. Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.
3. A statement outlining how ethical clearance has been obtained for the research, particularly concerning studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research must comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.
4. For research involving pharmacological agents, devices, or medical

technology, a clear Conflict of Interest statement concerning any funding from or pecuniary interests in companies could be perceived as a potential conflict of interest in the outcome of the research.

5. For clinical trials, these have been registered in a publically accessible database.

If the above items are not included in the cover letter, manuscripts cannot be sent for review.

Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word files need to be included upon submission: A title page file and the main text file that includes all parts of the text in the sequence indicated in the section 'Parts of the manuscript', including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using Microsoft Word, double-spaced. The top, bottom, and side margins should be 30 mm. All pages should be numbered consecutively in the top right-hand corner, beginning with the first page of the main text file.

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, low-resolution figures saved as .jpg or .bmp files should be uploaded, for ease of transmission during the review process. Upon acceptance of the article, high-resolution figures (at least 300 d.p.i.) saved as .eps or .tif files will be required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted papers will be passed to the production team for publication. The author identified as the formal corresponding author for the paper will receive an email, being asked to complete an electronic license agreement on behalf of all authors on the paper.

Accepted Articles

The accepted ‘in press’ manuscripts are published online very soon after acceptance, before copy-editing or typesetting. Accepted Articles are published online a few days after final acceptance, appear in PDF format only, are given a Digital Object Identifier (DOI), which allows them to be cited and tracked. After print publication, the DOI remains valid and can continue to be used to cite and access the article. Given that copyright licensing is a condition of publication, a completed copyright form is required before a manuscript can be processed as an Accepted Article.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing instructions on how to provide proof corrections to the article. It is therefore essential that a working e-mail address is provided for the corresponding author. Proofs should be corrected carefully; the responsibility for detecting errors lies with the author. The proof should be checked, and approval to publish the article should be emailed to the Publisher by the date indicated; otherwise, it may be signed off on by the Editor or held over to the next issue.

COPYRIGHT, LICENSING, AND ONLINE OPEN

Committee on Publication Ethics

The journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, except for Editorials, must contain an abstract of no more than 250 words. Abstracts for original articles should be formatted into subheadings, as detailed below. Titles must not be longer than 120 characters (including spaces).

Editorials

These are invited by the Editor-in-Chief or their delegated editor and should be a brief review of the subject concerned, regarding and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure, and cite up to 15 references, including the source article [this should be cited as Rom J Mil Med (year); (vol): [this issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine and advances in clinical practice. Most published reviews are in response to the editorial invitation, including thematically related “mini-series” of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are limited to 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes the submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for the preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer-review process. Meta-Analyses and Systematic Reviews have a word limit of 3500–5000 words, with an abstract of up to 250 words and up to 75 references, and 3–7 figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and/or historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Original articles are limited to 3000 words, with an abstract of up to 250 words and up to 50 references and 3–7 figures and tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Education and Imaging Coordinating Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features, and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as 'What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?' Part 2 will briefly describe the imaging features, particularly those that lead to a diagnosis or which are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, the presentation of analogous cases or related images from a similar case might be appropriate. Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background to and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors' revised 'Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication', as presented at http://www.ICMJE.org/.

Spelling. The journal uses US spelling and authors should, therefore, follow the latest edition of the Merriam-Webster's Collegiate Dictionary.

Units. All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations should be used sparingly and only where they ease the reader's task by reducing repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: title page; main text file; figures.

Title page

The title page should contain (i) a short informative title that contains the major keywords. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgments. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors' industrial links and affiliations. In the case of clinical trials or any article describing the use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer-reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented in the following order: (i) abstract and keywords, (ii) text, (iii) references, (iv) tables (each table complete with title and footnotes), (vii) figure legends. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 250 words or less the purpose, basic procedures, main findings, and principal conclusions of the study. Divide the abstract with the headings: *Background and Aim, Methods, Results, Conclusions*. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to five keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine's Medical Subject Headings (MeSH) browser—(http://www.nlm.nih.gov/mesh/meshhome.html).

Text

Authors should use subheadings to divide the sections of their manuscript: *Introduction, Methods, Results, Discussion Acknowledgments, and References*.

References

The Vancouver system of referencing should be used. In the text, references should be cited using Arabic numerals in square brackets in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or less; when seven or more list the first three followed by et al. Names of journals should be abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

References should be listed in the following form:

Number references in the order cited as Arabic numerals in square brackets on the line. Only literature that is published or in press (with the name of the publication known) may be numbered and listed; abstracts and letters to the editor may be cited, but they must be less than 3 years old and identified as such. Refer to only in the text, in parentheses, other material (manuscripts submitted, unpublished data, personal communications, and the like) as in the following example: (Chercheur X, unpublished data). If the owner of the unpublished data or personal communication is not an author of the manuscript under review, a signed statement is required verifying the accuracy of the attributed information and agreement to its publication. Use Index Medicus as the style guide for references and other journal abbreviations. List all authors up to six, using six and "et al." when the number is greater than six.

Tables

Tables should be self-contained and complement, but not duplicate, the information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table, legend, and footnotes must be understandable without reference to the text. Vertical lines should not be used to separate columns. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, §, ¶ should be used (in that order), and *, **, *** should be reserved for *P*-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication: Although low-quality images are adequate for review purposes, publication requires high-quality images to prevent the final product from being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at rjmilmed@yahoo.com

A cover letter containing an authorship statement should be included.

The cover letter should include a statement covering each of the following areas:

1. Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author.
2. Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.
3. A statement outlining how ethical clearance has been obtained for the research, particularly concerning studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research must comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.
4. For research involving pharmacological agents, devices, or medical

technology, a clear Conflict of Interest statement concerning any funding from or pecuniary interests in companies that could be perceived as a potential conflict of interest in the outcome of the research.

5. For clinical trials, these have been registered in a publically accessible database.

If the above items are not included in the cover letter, manuscripts cannot be sent for review.

Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word-files need to be included upon submission: A title page file and the main text file that includes all parts of the text in the sequence indicated in the section 'Parts of the manuscript', including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using Microsoft Word, double-spaced. The top, bottom, and side margins should be 30 mm. All pages should be numbered consecutively in the top right-hand corner, beginning with the first page of the main text file.

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, low-resolution figures saved as .jpg or .bmp files should be uploaded, for ease of transmission during the review process. Upon acceptance of the article, high-resolution figures (at least 300 d.p.i.) saved as .eps or .tif files will be required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted papers will be passed to the production team for publication. The author identified as the formal corresponding author for the paper will receive an email, being asked to complete an electronic license agreement on behalf of all authors on the paper.

Accepted Articles

The accepted ‘in press’ manuscripts are published online very soon after acceptance, before copy-editing or typesetting. Accepted Articles are published online a few days after final acceptance, appear in PDF format only, are given a Digital Object Identifier (DOI), which allows them to be cited and tracked. After print publication, the DOI remains valid and can continue to be used to cite and access the article. Given that copyright licensing is a condition of publication, a completed copyright form is required before a manuscript can be processed as an Accepted Article.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing instructions on how to provide proof corrections to the article. It is therefore essential that a working e-mail address is provided for the corresponding author. Proofs should be corrected carefully; the responsibility for detecting errors lies with the author. The proof should be checked, and approval to publish the article should be emailed to the Publisher by the date indicated; otherwise, it may be signed off on by the Editor or held over to the next issue.

COPYRIGHT, LICENSING AND ONLINE OPEN

ADMINISTRATIVE ISSUES

Guidelines for authors

Thank you for your interest in the *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully before submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review.

Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission following the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

We look forward to your submission.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians and Pharmacists. The Journal publishes peer-reviewed original papers, reviews, meta-analyses, and systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine.

Papers cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and historical aspects of the subject areas.

Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor will not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer-reviewed under the direction of an Editor. The Editor reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form, and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed following the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013) (http://www.wma.net/en/30publications/10policies/b3/index.html).

It should also state clearly in the text that all persons gave their informed consent before their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects from being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

(1) Accessible to the public at no charge;

(2) Searchable by standard, electronic (Internet-based) methods;

(3) Open to all prospective registrants free of charge or at minimal cost;

(4) Validates registered information;

(5) Identifies trials with a unique number; and

(6) includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of the last follow-up, the target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, except for Editorials, must contain an abstract of no more than 250 words. Abstracts for original articles should be formatted into subheadings, as detailed below. Titles must not be longer than 120 characters (including spaces).

Editorials

These are invited by the Editor-in-Chief or their delegated editor and should be a brief review of the subject concerned, regarding and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure, and cite up to 15 references, including the source article [this should be cited as Rom J Mil Med (year); (vol): [this issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine and advances in clinical practice. Most published reviews are in response to the editorial invitation, including thematically related "mini-series" of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are limited to 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes the submission of Meta-Analyses and Systematic

Reviews, which underpin evidence-based medicine. Guidelines for the preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer-review process. Meta-Analyses and Systematic Reviews have a word limit of 3500–5000 words, with an abstract of up to 250 words and up to 75 references, and 3–7 figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and/or historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Original articles are limited to 3000 words, with an abstract of up to 250 words and up to 50 references and 3–7 figures and tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Education and Imaging Coordinating Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features, and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as 'What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?' Part 2 will briefly describe the imaging features, particularly those that lead to a diagnosis or which are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, the presentation of analogous cases or related images from a similar case might be appropriate. Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background to and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors' revised 'Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication', as presented at http://www.ICMJE.org/.

Spelling. The journal uses US spelling and authors should, therefore, follow the latest edition of the Merriam-Webster's Collegiate Dictionary.

Units. All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations should be used sparingly and only where they ease the reader's task by reducing repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: title page; main text file; figures.

Title page

The title page should contain (i) a short informative title that contains the major keywords. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgments. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors' industrial links and affiliations. In the case of clinical trials or any article describing the use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer-reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented in the following order: (i) abstract and keywords, (ii) text, (iii) references, (iv) tables (each table complete with title and footnotes), (vii) figure legends. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 250 words or less the purpose, basic procedures, main findings, and principal conclusions of the study. Divide the abstract with the headings: *Background and Aim, Methods, Results, Conclusions*. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to five keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine's Medical Subject Headings (MeSH) browser—(http://www.nlm.nih.gov/mesh/meshhome.html).

Text

Authors should use subheadings to divide the sections of their manuscript: *Introduction, Methods, Results, Discussion Acknowledgments, and References*.

References

The Vancouver system of referencing should be used. In the text, references should be cited using Arabic numerals in square brackets in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or less; when seven or more list the first three followed by et al. Names of journals should be abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

References should be listed in the following form:

Number references in the order cited as Arabic numerals in parentheses on the line. Only literature that is published or in press (with the name of the publication known) may be numbered and listed; abstracts and letters to the editor may be cited, but they must be less than 3 years old and identified as such. Refer to only in the text, in parentheses, other material (manuscripts submitted, unpublished data, personal communications, and the like) as in the following example: (Chercheur X, unpublished data). If the owner of the unpublished data or personal communication is not an author of the manuscript under review, a signed statement is required verifying the accuracy of the attributed information and agreement to its publication. Use Index Medicus as the style guide for references and other journal abbreviations. List all authors up to six, using six and "et al." when the number is greater than six.

Tables

Tables should be self-contained and complement, but not duplicate, the information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table, legend, and footnotes must be understandable without reference to the text. Vertical lines should not be used to separate columns. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, §, ¶ should be used (in that order), and *, **, *** should be reserved for *P*-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication: Although low-quality images are adequate for review purposes, publication requires high-quality images to prevent the final product from being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at rjmilmed@yahoo.com
A cover letter containing an authorship statement should be included.
The cover letter should include a statement covering each of the following areas:

1. Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author.
2. Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.
3. A statement outlining how ethical clearance has been obtained for the research, particularly concerning studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research must comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.
4. For research involving pharmacological agents, devices, or medical technology, a clear Conflict of Interest statement concerning any funding from or pecuniary interests in companies that could be perceived as a potential conflict of interest in the outcome of the research.
5. For clinical trials, these have been registered in a publically accessible database.

If the above items are not included in the cover letter, manuscripts cannot be sent for review.
Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.
Two Word-files need to be included upon submission: A title page file and the main text file that includes all parts of the text in the sequence indicated in the section 'Parts of the manuscript', including tables and figure legends but excluding figures which should be supplied separately.
The main text file should be prepared using Microsoft Word, double-spaced. The top, bottom, and side margins should be 30 mm. All pages should be numbered consecutively in the top right-hand corner, beginning with the first page of the main text file.
Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, low-resolution figures saved as .jpg or .bmp files should be uploaded, for ease of transmission during the review process. Upon acceptance of the article, high-resolution figures (at least 300 d.p.i.) saved as .eps or .tif files will be required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted papers will be passed to the production team for publication. The author identified as the formal corresponding author for the paper will receive an email, being asked to complete an electronic license agreement on behalf of all authors on the paper.

Accepted Articles

The accepted ‘in press’ manuscripts are published online very soon after acceptance, before copy-editing or typesetting. Accepted Articles are published online a few days after final acceptance, appear in PDF format only, are given a Digital Object Identifier (DOI), which allows them to be cited and tracked. After print publication, the DOI remains valid and can continue to be used to cite and access the article. Given that copyright licensing is a condition of publication, a completed copyright form is required before a manuscript can be processed as an Accepted Article.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing instructions on how to provide proof corrections to the article. It is therefore essential that a working e-mail address is provided for the corresponding author. Proofs should be corrected carefully; the responsibility for detecting errors lies with the author. The proof should be checked, and approval to publish the article should be emailed to the Publisher by the date indicated; otherwise, it may be signed off on by the Editor or held over to the next issue.

COPYRIGHT, LICENSING AND ONLINE OPEN

Details are on the Copyright Agreement Form that must be completed and signed when the Article is accepted.

ADMINISTRATIVE ISSUES

Guidelines for authors

Thank you for your interest in *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully prior to submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review.

Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission in accordance with the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

We look forward to your submission.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians and Pharmacists. The Journal publishes peer-reviewed original papers, reviews, meta-analyses and systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine.

Papers cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and historical aspects of the subject areas.

Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor will not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer reviewed under the direction of an Editor. The Editor reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed in accordance with the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013), available at http://www.wma.net/en/30publications/10policies/b3/index.html. It should also state clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

(1) Accessible to the public at no charge;

(2) Searchable by standard, electronic (Internet-based) methods;

(3) Open to all prospective registrants free of charge or at minimal cost;

(4) Validates registered information;

(5) Identifies trials with a unique number; and

(6) includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of last follow-up, target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, with the exception of Editorials, must contain an abstract of no more than 250 words. Abstracts for original articles should be formatted into subheadings, as detailed below. Titles must not be longer than 120 characters (including spaces).

Editorials

These are invited by the Editor-in-Chief or their delegated editor, and should be a brief review of the subject concerned, with reference to and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure and cite up to 15 references, including the source article [this should be cited as Military Med. Today (year); (vol): [this issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine, and advances in clinical practice. Most published

reviews are in response to editorial invitation, including thematically related “mini-series” of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are limited to 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer review process. Meta-Analyses and Systematic Reviews have a word limit of 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and/or historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Original articles are limited to 3000 words, with an abstract of up to 250 words and up to 50 references and 3–7 figures and tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Education and Imaging Coordinating Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as ‘What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?’ Part 2 will briefly describe the imaging features, particularly those that lead to diagnosis or which are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, presentation of analogous cases or related images from a similar case might be appropriate. Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background to and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors’ revised ‘Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication’, as presented at http://www.ICMJE.org/.

Spelling. The journal uses US spelling and authors should therefore follow the latest edition of the Merriam-Webster’s Collegiate Dictionary.

Units. All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations should be used sparingly and only where they ease the reader’s task by reducing repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: title page; main text file; figures.

Title page

The title page should contain (i) a short informative title that contains the major key words. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgements. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors’ industrial links and affiliations. In the case of clinical trials or any article describing use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented in the following order: (i) abstract and key words, (ii) text, (iii) references, (iv) tables (each table complete with title and footnotes), (vii) figure legends. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 250 words or less the purpose, basic procedures, main findings and principal conclusions of the study. Divide the abstract with the headings: *Background and Aim, Methods, Results, Conclusions*. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to five keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine’s Medical Subject Headings (MeSH) browser—(http://www.nlm.nih.gov/mesh/meshhome.html).

Text

Authors should use subheadings to divide the sections of their manuscript: *Introduction, Methods, Results, Discussion Acknowledgments and References*.

References

The Vancouver system of referencing should be used. In the text, references should be cited using superscript Arabic numerals in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or less; when seven or more list the first three followed by et al. Names of journals should be

abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

References should be listed in the following form:

Number references in the order cited as Arabic numerals in parentheses on the line. Only literature that is published or in press (with the name of the publication known) may be numbered and listed; abstracts and letters to the editor may be cited, but they must be less than 3 years old and identified as such. Refer to only in the text, in parentheses, other material (manuscripts submitted, unpublished data, personal communications, and the like) as in the following example: (Chercheur X, unpublished data). If the owner of the unpublished data or personal communication is not an author of the manuscript under review, a signed statement is required verifying the accuracy of the attributed information and agreement to its publication. Use Index Medicus as the style guide for references and other journal abbreviations. List all authors up to six, using six and "et al." when the number is greater than six.

Tables

Tables should be self-contained and complement, but not duplicate, information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table, legend and footnotes must be understandable without reference to the text. Vertical lines should not be used to separate columns. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, §, ¶ should be used (in that order) and *, **, *** should be reserved for *P*-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication: Although low quality images are adequate for review purposes, publication requires high quality images to prevent the final product being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at rjmilmed@yahoo.com

A cover letter containing an authorship statement should be included.

The cover letter should include a statement covering each of the following areas:

1. Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author.
2. Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.
3. A statement outlining how ethical clearance has been obtained for the research, particularly in relation to studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research must comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.
4. For research involving pharmacological agents, devices or medical technology, a clear Conflict of Interest statement in relation to any funding from or pecuniary interests in companies that could be perceived as a potential conflict of interest in the outcome of the research.
5. For clinical trials, that these have been registered in a publically accessible database.

If the above items are not included in the cover letter, manuscripts cannot be sent for review.

Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word-files need to be included upon submission: A title page file and a main text file that includes all parts of the text in the sequence indicated in the section 'Parts of the manuscript', including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using Microsoft Word, doubled-spaced. The top, bottom and side margins should be 30 mm. All pages should be numbered consecutively in the top right-hand corner, beginning with the first page of the main text file.

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, low-resolution figures saved as .jpg or .bmp files should be uploaded, for ease of transmission during the review process. Upon acceptance of the article, high-resolution figures (at least 300 d.p.i.) saved as .eps or .tif files will be required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted papers will be passed to production team for publication. The author identified as the formal corresponding author for the paper will receive an email, being asked to complete an electronic license agreement on behalf of all authors on the paper.

Accepted Articles

The accepted ‘in press’ manuscripts are published online very soon after acceptance, prior to copy-editing or typesetting. Accepted Articles are published online a few days after final acceptance, appear in PDF format only, are given a Digital Object Identifier (DOI), which allows them to be cited and tracked. After print publication, the DOI remains valid and can continue to be used to cite and access the article. Given that copyright licensing is a condition of publication, a completed copyright form is required before a manuscript can be processed as an Accepted Article.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing instructions on how to provide proof corrections to the article. It is therefore essential that a working e-mail address is provided for the corresponding author. Proofs should be corrected carefully; the responsibility for detecting errors lies with the author. The proof should be checked, and approval to publish the article should be emailed to the Publisher by the date indicated; otherwise, it may be signed off on by the Editor or held over to the next issue.

Offprint

A PDF reprint of the article will be supplied free of charge to the corresponding author. Additional printed offprint may be ordered for a fee.

COPYRIGHT, LICENSING AND ONLINE OPEN

Details are on the Copyright Agreement Form that must be completed and signed when the Article is accepted.

Guidelines for authors

Thank you for your interest in *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully prior to submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review.

Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission in accordance with the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

We look forward to your submission.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians and Pharmacists. The Journal publishes peer-reviewed original papers, reviews, meta-analyses and systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine.

Papers cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and historical aspects of the subject areas.

Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor will not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer reviewed under the direction of an Editor. The Editor reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed in accordance with the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013), available at http://www.wma.net/en/30publications/10policies/b3/index.html. It should also state clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

(1) Accessible to the public at no charge;
(2) Searchable by standard, electronic (Internet-based) methods;
(3) Open to all prospective registrants free of charge or at minimal cost;
(4) Validates registered information;
(5) Identifies trials with a unique number; and
(6) includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of last follow-up, target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, with the exception of Editorials, must contain an abstract of no more than 250 words. Abstracts for original articles should be formatted into subheadings, as detailed below. Titles must not be longer than 120 characters (including spaces).

Editorials

These are invited by the Editor-in-Chief or their delegated editor, and should be a brief review of the subject concerned, with reference to and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure and cite up to 15 references, including the source article [this should be cited as Military Med. Today (year); (vol): [this issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine, and advances in clinical practice. Most published

reviews are in response to editorial invitation, including thematically related “mini-series” of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are limited to 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer review process. Meta-Analyses and Systematic Reviews have a word limit of 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and/or historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Original articles are limited to 3000 words, with an abstract of up to 250 words and up to 50 references and 3–7 figures and tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Education and Imaging Coordinating Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as ‘What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?’ Part 2 will briefly describe the imaging features, particularly those that lead to diagnosis or which are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, presentation of analogous cases or related images from a similar case might be appropriate. Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background to and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors’ revised ‘Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication’, as presented at http://www.ICMJE.org/.

Spelling. The journal uses US spelling and authors should therefore follow the latest edition of the Merriam-Webster’s Collegiate Dictionary.

Units. All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations should be used sparingly and only where they ease the reader’s task by reducing repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: title page; main text file; figures.

Title page

The title page should contain (i) a short informative title that contains the major key words. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgements. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors’ industrial links and affiliations. In the case of clinical trials or any article describing use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented in the following order: (i) abstract and key words, (ii) text, (iii) references, (iv) tables (each table complete with title and footnotes), (vii) figure legends. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 250 words or less the purpose, basic procedures, main findings and principal conclusions of the study. Divide the abstract with the headings: *Background and Aim, Methods, Results, Conclusions*. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to five keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine’s Medical Subject Headings (MeSH) browser—(http://www.nlm.nih.gov/mesh/meshhome.html).

Text

Authors should use subheadings to divide the sections of their manuscript: *Introduction, Methods, Results, Discussion Acknowledgments and References*.

References

The Vancouver system of referencing should be used. In the text, references should be cited using superscript Arabic numerals in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or less; when seven or more list the first three followed by et al. Names of journals should be

abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

References should be listed in the following form:

Number references in the order cited as Arabic numerals in parentheses on the line. Only literature that is published or in press (with the name of the publication known) may be numbered and listed; abstracts and letters to the editor may be cited, but they must be less than 3 years old and identified as such. Refer to only in the text, in parentheses, other material (manuscripts submitted, unpublished data, personal communications, and the like) as in the following example: (Chercheur X, unpublished data). If the owner of the unpublished data or personal communication is not an author of the manuscript under review, a signed statement is required verifying the accuracy of the attributed information and agreement to its publication. Use Index Medicus as the style guide for references and other journal abbreviations. List all authors up to six, using six and "et al." when the number is greater than six.

Tables

Tables should be self-contained and complement, but not duplicate, information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table, legend and footnotes must be understandable without reference to the text. Vertical lines should not be used to separate columns. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, §, ¶ should be used (in that order) and *, **, *** should be reserved for *P*-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication: Although low quality images are adequate for review purposes, publication requires high quality images to prevent the final product being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at rjmilmed@yahoo.com

A cover letter containing an authorship statement should be included.

The cover letter should include a statement covering each of the following areas:

1. Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author.
2. Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.
3. A statement outlining how ethical clearance has been obtained for the research, particularly in relation to studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research must comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.
4. For research involving pharmacological agents, devices or medical technology, a clear Conflict of Interest statement in relation to any funding from or pecuniary interests in companies that could be perceived as a potential conflict of interest in the outcome of the research.
5. For clinical trials, that these have been registered in a publically accessible database.

If the above items are not included in the cover letter, manuscripts cannot be sent for review.

Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word-files need to be included upon submission: A title page file and a main text file that includes all parts of the text in the sequence indicated in the section 'Parts of the manuscript', including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using Microsoft Word, doubled-spaced. The top, bottom and side margins should be 30 mm. All pages should be numbered consecutively in the top right-hand corner, beginning with the first page of the main text file.

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, low-resolution figures saved as .jpg or .bmp files should be uploaded, for ease of transmission during the review process. Upon acceptance of the article, high-resolution figures (at least 300 d.p.i.) saved as .eps or .tif files will be required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted papers will be passed to production team for publication. The author identified as the formal corresponding author for the paper will receive an email, being asked to complete an electronic license agreement on behalf of all authors on the paper.

Accepted Articles

The accepted 'in press' manuscripts are published online very soon after acceptance, prior to copy-editing or typesetting. Accepted Articles are published online a few days after final acceptance, appear in PDF format only, are given a Digital Object Identifier (DOI), which allows them to be cited and tracked. After print publication, the DOI remains valid and can continue to be used to cite and access the article. Given that copyright licensing is a condition of publication, a completed copyright form is required before a manuscript can be processed as an Accepted Article.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing instructions on how to provide proof corrections to the article. It is therefore essential that a working e-mail address is provided for the corresponding author. Proofs should be corrected carefully; the responsibility for detecting errors lies with the author. The proof should be checked, and approval to publish the article should be emailed to the Publisher by the date indicated; otherwise, it may be signed off on by the Editor or held over to the next issue.

Offprint

A PDF reprint of the article will be supplied free of charge to the corresponding author. Additional printed offprint may be ordered for a fee.

COPYRIGHT, LICENSING AND ONLINE OPEN

Details are on the Copyright Agreement Form that must be completed and signed when the Article is accepted.

Guidelines for authors

Thank you for your interest in *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully prior to submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review.

Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission in accordance with the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

We look forward to your submission.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians and Pharmacists. The Journal publishes peer-reviewed original papers, reviews, meta-analyses and systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine.

Papers cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and historical aspects of the subject areas.

Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor will not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer reviewed under the direction of an Editor. The Editor reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed in accordance with the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013) (http://www.wma.net/en/30publications/10policies/b3/index.html).

It should also state clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

(1) Accessible to the public at no charge;
(2) Searchable by standard, electronic (Internet-based) methods;

Guidelines for authors

Thank you for your interest in the *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully before submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review.

Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission following the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

We look forward to your submission.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians and Pharmacists. The Journal publishes peer-reviewed original papers, reviews, meta-analyses, and systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine.

Papers cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and historical aspects of the subject areas.

Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor will not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer-reviewed under the direction of an Editor. The Editor reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form, and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed following the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013) (http://www.wma.net/en/30publications/10policies/b3/index.html).

It should also state clearly in the text that all persons gave their informed consent before their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects from being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

(1) Accessible to the public at no charge;
(2) Searchable by standard, electronic (Internet-based) methods;
(3) Open to all prospective registrants free of charge or at minimal cost;
(4) Validates registered information;
(5) Identifies trials with a unique number; and
(6) includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of the last follow-up, the target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, except for Editorials, must contain an abstract of no more than 250 words. Abstracts for original articles should be formatted into subheadings, as detailed below. Titles must not be longer than 120 characters (including spaces).

Editorials

These are invited by the Editor-in-Chief or their delegated editor and should be a brief review of the subject concerned, regarding and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure, and cite up to 15 references, including the source article [this should be cited as Rom J Mil Med (year); (vol): [this issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine and advances in clinical practice. Most published reviews are in response to the editorial invitation, including thematically related “mini-series” of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are limited to 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes the submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for the preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer-review process. Meta-Analyses and Systematic Reviews have a word limit of 3500–5000 words, with an abstract of up to 250 words and up to 75 references, and 3–7 figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and/or historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Original articles are limited to 3000 words, with an abstract of up to 250 words and up to 50 references and 3–7 figures and tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Education and Imaging Coordinating Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features, and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as 'What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?' Part 2 will briefly describe the imaging features, particularly those that lead to a diagnosis or which are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, the presentation of analogous cases or related images from a similar case might be appropriate. Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background to and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors' revised 'Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication', as presented at http://www.ICMJE.org/.

Spelling. The journal uses US spelling and authors should, therefore, follow the latest edition of the Merriam-Webster's Collegiate Dictionary.

Units. All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations should be used sparingly and only where they ease the reader's task by reducing repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: title page; main text file; figures.

Title page

The title page should contain (i) a short informative title that contains the major keywords. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgments. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors' industrial links and affiliations. In the case of clinical trials or any article describing the use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer-reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented in the following order: (i) abstract and keywords, (ii) text, (iii) references, (iv) tables (each table complete with title and footnotes), (vii) figure legends. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 250 words or less the purpose, basic procedures, main findings, and principal conclusions of the study. Divide the abstract with the headings: *Background and Aim, Methods, Results, Conclusions*. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to five keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine's Medical Subject Headings (MeSH) browser—(http://www.nlm.nih.gov/mesh/meshhome.html).

Text

Authors should use subheadings to divide the sections of their manuscript: *Introduction, Methods, Results, Discussion Acknowledgments, and References*.

References

The Vancouver system of referencing should be used. In the text, references should be cited using superscript Arabic numerals in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or less; when seven or more list the first three followed by et al. Names of journals should be abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

References should be listed in the following form:

Number references in the order cited as Arabic numerals in parentheses on the line. Only literature that is published or in press (with the name of the publication known) may be numbered and listed; abstracts and letters to the editor may be cited, but they must be less than 3 years old and identified as such. Refer to only in the text, in parentheses, other material (manuscripts submitted, unpublished data, personal communications, and the like) as in the following example: (Chercheur X, unpublished data). If the owner of the unpublished data or personal communication is not an author of the manuscript under review, a signed statement is required verifying the accuracy of the attributed information and agreement to its publication. Use Index Medicus as the style guide for references and other journal abbreviations. List all authors up to six, using six and "et al." when the number is greater than six.

Tables

Tables should be self-contained and complement, but not duplicate, the information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table, legend, and footnotes must be understandable without reference to the text. Vertical lines should not be used to separate columns. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, §, ¶ should be used (in that order), and *, **, *** should be reserved for *P*-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication: Although low-quality images are adequate for review purposes, publication requires high-quality images to prevent the final product from being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at rjmilmed@yahoo.com

A cover letter containing an authorship statement should be included.

The cover letter should include a statement covering each of the following areas:

1. Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author.
2. Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.
3. A statement outlining how ethical clearance has been obtained for the research, particularly concerning studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research must comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.
4. For research involving pharmacological agents, devices, or medical

technology, a clear Conflict of Interest statement concerning any funding from or pecuniary interests in companies that could be perceived as a potential conflict of interest in the outcome of the research.

5. For clinical trials, these have been registered in a publically accessible database.

If the above items are not included in the cover letter, manuscripts cannot be sent for review.

Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word-files need to be included upon submission: A title page file and the main text file that includes all parts of the text in the sequence indicated in the section 'Parts of the manuscript', including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using Microsoft Word, double-spaced. The top, bottom, and side margins should be 30 mm. All pages should be numbered consecutively in the top right-hand corner, beginning with the first page of the main text file.

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, low-resolution figures saved as .jpg or .bmp files should be uploaded, for ease of transmission during the review process. Upon acceptance of the article, high-resolution figures (at least 300 d.p.i.) saved as .eps or .tif files will be required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted papers will be passed to the production team for publication. The author identified as the formal corresponding author for the paper will receive an email, being asked to complete an electronic license agreement on behalf of all authors on the paper.

Accepted Articles

The accepted ‘in press’ manuscripts are published online very soon after acceptance, before copy-editing or typesetting. Accepted Articles are published online a few days after final acceptance, appear in PDF format only, are given a Digital Object Identifier (DOI), which allows them to be cited and tracked. After print publication, the DOI remains valid and can continue to be used to cite and access the article. Given that copyright licensing is a condition of publication, a completed copyright form is required before a manuscript can be processed as an Accepted Article.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing instructions on how to provide proof corrections to the article. It is therefore essential that a working e-mail address is provided for the corresponding author. Proofs should be corrected carefully; the responsibility for detecting errors lies with the author. The proof should be checked, and approval to publish the article should be emailed to the Publisher by the date indicated; otherwise, it may be signed off on by the Editor or held over to the next issue.

Offprint

A PDF reprint of the article will be supplied free of charge to the corresponding author. Additional printed offprints may be ordered for a fee.

COPYRIGHT, LICENSING AND ONLINE OPEN

Details are on the Copyright Agreement Form that must be completed and signed when the Article is accepted.

Guidelines for authors

Thank you for your interest in *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully prior to submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review.

Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission in accordance with the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

We look forward to your submission.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians and Pharmacists. The Journal publishes peer-reviewed original papers, reviews, meta-analyses and systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine.

Papers cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and historical aspects of the subject areas.

Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor will not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer reviewed under the direction of an Editor. The Editor reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed in accordance with the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013), available at http://www.wma.net/en/30publications/10policies/b3/index.html. It should also state clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

(1) Accessible to the public at no charge;
(2) Searchable by standard, electronic (Internet-based) methods;
(3) Open to all prospective registrants free of charge or at minimal cost;
(4) Validates registered information;
(5) Identifies trials with a unique number; and
(6) includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of last follow-up, target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, with the exception of Editorials, must contain an abstract of no more than 250 words. Abstracts for original articles should be formatted into subheadings, as detailed below. Titles must not be longer than 120 characters (including spaces).

Editorials

These are invited by the Editor-in-Chief or their delegated editor, and should be a brief review of the subject concerned, with reference to and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure and cite up to 15 references, including the source article [this should be cited as Military Med. Today (year); (vol): [this issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine, and advances in clinical practice. Most published reviews are in response to editorial invitation, including thematically related “mini-series” of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are limited to 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer review process. Meta-Analyses and Systematic Reviews have a word limit of 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and/or historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Original articles are limited to 3000 words, with an abstract of up to 250 words and up to 50 references and 3–7 figures and tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Education and Imaging Coordinating Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as ‘What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?’ Part 2 will briefly describe the imaging features, particularly those that lead to diagnosis or which are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, presentation of analogous cases or related images from a similar case might be appropriate. Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background to and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors’ revised ‘Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication’, as presented at http://www.ICMJE.org/.

Spelling. The journal uses US spelling and authors should therefore follow the latest edition of the Merriam-Webster’s Collegiate Dictionary.

Units. All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations should be used sparingly and only where they ease the reader’s task by reducing repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: title page; main text file; figures.

Title page

The title page should contain (i) a short informative title that contains the major key words. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgements. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors’ industrial links and affiliations. In the case of clinical trials or any article describing use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented in the following order: (i) abstract and key words, (ii) text, (iii) references, (iv) tables (each table complete with title and footnotes), (vii) figure legends. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 250 words or less the purpose, basic procedures, main findings and principal conclusions of the study. Divide the abstract with the headings: *Background and Aim, Methods, Results, Conclusions*. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to five keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine’s Medical Subject Headings (MeSH) browser—(http://www.nlm.nih.gov/mesh/meshhome.html).

Text

Authors should use subheadings to divide the sections of their manuscript: *Introduction, Methods, Results, Discussion Acknowledgements and References*.

References

The Vancouver system of referencing should be used. In the text, references should be cited using superscript Arabic numerals in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or less; when seven or more list the first three followed by et al. Names of journals should be abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

References should be listed in the following form:

Number references in the order cited as Arabic numerals in parentheses on the line. Only literature that is published or in press (with the name of the publication known) may be numbered and listed; abstracts and letters to the editor may be cited, but they must be less than 3 years old and identified as such. Refer to only in the text, in parentheses, other material (manuscripts submitted, unpublished data, personal communications, and the like) as in the following example: (Chercheur X, unpublished data). If the owner of the unpublished data or personal communication is not an author of the manuscript under review, a signed statement is required verifying the accuracy of the attributed information and agreement to its publication. Use Index Medicus as the style guide for references and other journal abbreviations. List all authors up to six, using six and "et al." when the number is greater than six.

Tables

Tables should be self-contained and complement, but not duplicate, information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table, legend and footnotes must be understandable without reference to the text. Vertical lines should not be used to separate columns. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, §, ¶ should be used (in that order) and *, **, *** should be reserved for *P*-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication: Although low quality images are adequate for review purposes, publication requires high quality images to prevent the final product being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at rjmilmed@yahoo.com

A cover letter containing an authorship statement should be included.

The cover letter should include a statement covering each of the following areas:

1. Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author.
2. Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.
3. A statement outlining how ethical clearance has been obtained for the research, particularly in relation to studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research must comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.
4. For research involving pharmacological agents, devices or medical technology, a clear Conflict of Interest statement in relation to any funding from or pecuniary interests in companies that could be perceived as a potential conflict of interest in the outcome of the research.
5. For clinical trials, that these have been registered in a publically accessible database.

If the above items are not included in the cover letter, manuscripts cannot be sent for review.

Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word-files need to be included upon submission: A title page file and a main text file that includes all parts of the text in the sequence indicated in the section 'Parts of the manuscript', including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using Microsoft Word, doubled-spaced. The top, bottom and side margins should be 30 mm. All pages should be numbered consecutively in the top right-hand corner, beginning with the first page of the main text file.

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, low-resolution figures saved as .jpg or .bmp files should be uploaded, for ease of transmission during the review process. Upon acceptance of the article, high-resolution figures (at least 300 d.p.i.) saved as .eps or .tif files will be required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted papers will be passed to production team for publication. The author identified as the formal corresponding author for the paper will receive an email, being asked to complete an electronic license agreement on behalf of all authors on the paper.

Accepted Articles

The accepted ‘in press’ manuscripts are published online very soon after acceptance, prior to copy-editing or typesetting. Accepted Articles are published online a few days after final acceptance, appear in PDF format only, are given a Digital Object Identifier (DOI), which allows them to be cited and tracked. After print publication, the DOI remains valid and can continue to be used to cite and access the article. Given that copyright licensing is a condition of publication, a completed copyright form is required before a manuscript can be processed as an Accepted Article.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing instructions on how to provide proof corrections to the article. It is therefore essential that a working e-mail address is provided for the corresponding author. Proofs should be corrected carefully; the responsibility for detecting errors lies with the author. The proof should be checked, and approval to publish the article should be emailed to the Publisher by the date indicated; otherwise, it may be signed off on by the Editor or held over to the next issue.

Offprint

A PDF reprint of the article will be supplied free of charge to the corresponding author. Additional printed offprint may be ordered for a fee.

COPYRIGHT, LICENSING AND ONLINE OPEN

Details are on the Copyright Agreement Form that must be completed and signed when the Article is accepted.

ADMINISTRATIVE ISSUES

Guidelines for authors

Thank you for your interest in *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully prior to submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review.

Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission in accordance with the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

We look forward to your submission.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians and Pharmacists. The Journal publishes peer-reviewed original papers, reviews, meta-analyses and systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine.

Papers cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and historical aspects of the subject areas.

Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor will not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer reviewed under the direction of an Editor. The Editor reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed in accordance with the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013), available at http://www.wma.net/en/30publications/10policies/b3/index.html. It should also state clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

(1) Accessible to the public at no charge;
(2) Searchable by standard, electronic (Internet-based) methods;
(3) Open to all prospective registrants free of charge or at minimal cost;
(4) Validates registered information;
(5) Identifies trials with a unique number; and
(6) includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of last follow-up, target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, with the exception of Editorials, must contain an abstract of no more than 250 words. Abstracts for original articles should be formatted into subheadings, as detailed below. Titles must not be longer than 120 characters (including spaces).

Editorials

These are invited by the Editor-in-Chief or their delegated editor, and should be a brief review of the subject concerned, with reference to and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure and cite up to 15 references, including the source article [this should be cited as Military Med. Today (year); (vol): [this issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine, and advances in clinical practice. Most published

reviews are in response to editorial invitation, including thematically related “mini-series” of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are limited to 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer review process. Meta-Analyses and Systematic Reviews have a word limit of 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and/or historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Original articles are limited to 3000 words, with an abstract of up to 250 words and up to 50 references and 3–7 figures and tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Education and Imaging Coordinating Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as ‘What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?’ Part 2 will briefly describe the imaging features, particularly those that lead to diagnosis or which are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, presentation of analogous cases or related images from a similar case might be appropriate. Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background to and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors’ revised ‘Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication’, as presented at http://www.ICMJE.org/.

Spelling. The journal uses US spelling and authors should therefore follow the latest edition of the Merriam-Webster’s Collegiate Dictionary.

Units. All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations should be used sparingly and only where they ease the reader’s task by reducing repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: title page; main text file; figures.

Title page

The title page should contain (i) a short informative title that contains the major key words. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgements. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors’ industrial links and affiliations. In the case of clinical trials or any article describing use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented in the following order: (i) abstract and key words, (ii) text, (iii) references, (iv) tables (each table complete with title and footnotes), (vii) figure legends. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 250 words or less the purpose, basic procedures, main findings and principal conclusions of the study. Divide the abstract with the headings: *Background and Aim, Methods, Results, Conclusions*. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to five keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine’s Medical Subject Headings (MeSH) browser—(http://www.nlm.nih.gov/mesh/meshhome.html).

Text

Authors should use subheadings to divide the sections of their manuscript: *Introduction, Methods, Results, Discussion Acknowledgments and References*.

References

The Vancouver system of referencing should be used. In the text, references should be cited using superscript Arabic numerals in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or less; when seven or more list the first three followed by et al. Names of journals should be

abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

References should be listed in the following form:

Number references in the order cited as Arabic numerals in parentheses on the line. Only literature that is published or in press (with the name of the publication known) may be numbered and listed; abstracts and letters to the editor may be cited, but they must be less than 3 years old and identified as such. Refer to only in the text, in parentheses, other material (manuscripts submitted, unpublished data, personal communications, and the like) as in the following example: (Chercheur X, unpublished data). If the owner of the unpublished data or personal communication is not an author of the manuscript under review, a signed statement is required verifying the accuracy of the attributed information and agreement to its publication. Use Index Medicus as the style guide for references and other journal abbreviations. List all authors up to six, using six and "et al." when the number is greater than six.

Tables

Tables should be self-contained and complement, but not duplicate, information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table, legend and footnotes must be understandable without reference to the text. Vertical lines should not be used to separate columns. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, §, ¶ should be used (in that order) and *, **, *** should be reserved for *P*-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication: Although low quality images are adequate for review purposes, publication requires high quality images to prevent the final product being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at rjmilmed@yahoo.com

A cover letter containing an authorship statement should be included.

The cover letter should include a statement covering each of the following areas:

1. Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author.
2. Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.
3. A statement outlining how ethical clearance has been obtained for the research, particularly in relation to studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research must comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.
4. For research involving pharmacological agents, devices or medical technology, a clear Conflict of Interest statement in relation to any funding from or pecuniary interests in companies that could be perceived as a potential conflict of interest in the outcome of the research.
5. For clinical trials, that these have been registered in a publically accessible database.

If the above items are not included in the cover letter, manuscripts cannot be sent for review.

Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word-files need to be included upon submission: A title page file and a main text file that includes all parts of the text in the sequence indicated in the section 'Parts of the manuscript', including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using Microsoft Word, doubled-spaced. The top, bottom and side margins should be 30 mm. All pages should be numbered consecutively in the top right-hand corner, beginning with the first page of the main text file.

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, low-resolution figures saved as .jpg or .bmp files should be uploaded, for ease of transmission during the review process. Upon acceptance of the article, high-resolution figures (at least 300 d.p.i.) saved as .eps or .tif files will be required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted papers will be passed to production team for publication. The author identified as the formal corresponding author for the paper will receive an email, being asked to complete an electronic license agreement on behalf of all authors on the paper.

Accepted Articles

The accepted 'in press' manuscripts are published online very soon after acceptance, prior to copy-editing or typesetting. Accepted Articles are published online a few days after final acceptance, appear in PDF format only, are given a Digital Object Identifier (DOI), which allows them to be cited and tracked. After print publication, the DOI remains valid and can continue to be used to cite and access the article. Given that copyright licensing is a condition of publication, a completed copyright form is required before a manuscript can be processed as an Accepted Article.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing instructions on how to provide proof corrections to the article. It is therefore essential that a working e-mail address is provided for the corresponding author. Proofs should be corrected carefully; the responsibility for detecting errors lies with the author. The proof should be checked, and approval to publish the article should be emailed to the Publisher by the date indicated; otherwise, it may be signed off on by the Editor or held over to the next issue.

Offprint

A PDF reprint of the article will be supplied free of charge to the corresponding author. Additional printed offprint may be ordered for a fee.

COPYRIGHT, LICENSING AND ONLINE OPEN

Details are on the Copyright Agreement Form that must be completed and signed when the Article is accepted.

Guidelines for authors

Thank you for your interest in *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully prior to submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review.

Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission in accordance with the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

We look forward to your submission.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians and Pharmacists. The Journal publishes peer-reviewed original papers, reviews, meta-analyses and systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine.

Papers cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and historical aspects of the subject areas.

Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor will not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer reviewed under the direction of an Editor. The Editor reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed in accordance with the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013), available at http://www.wma.net/en/30publications/10policies/b3/index.html. It should also state clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

(1) Accessible to the public at no charge;

(2) Searchable by standard, electronic (Internet-based) methods;

(3) Open to all prospective registrants free of charge or at minimal cost;

(4) Validates registered information;

(5) Identifies trials with a unique number; and

(6) includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of last follow-up, target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that

your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, with the exception of Editorials, must contain an abstract of no more than 250 words. Abstracts for original articles should be formatted into subheadings, as detailed below. Titles must not be longer than 120 characters (including spaces).

Editorials

These are invited by the Editor-in-Chief or their delegated editor, and should be a brief review of the subject concerned, with reference to and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure and cite up to 15 references, including the source article [this should be cited as Military Med. Today (year); (vol): [this issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine, and advances in clinical practice. Most published reviews are in response to editorial invitation, including thematically related “mini-series” of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are limited to 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer review process. Meta-Analyses and Systematic Reviews have a word limit of 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and/or historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Original articles are limited to 3000 words, with an abstract of up to 250 words and up to 50 references and 3–7 figures and tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Education and Imaging Coordinating Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as ‘What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?’ Part 2 will briefly describe the imaging features, particularly those that lead to diagnosis or which are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, presentation of analogous cases or related images from a similar case might be appropriate. Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background to and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors’ revised ‘Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication’, as presented at http://www.ICMJE.org/.

Spelling. The journal uses US spelling and authors should therefore follow the latest edition of the Merriam-Webster’s Collegiate Dictionary.

Units. All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations should be used sparingly and only where they ease the reader’s task by reducing repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: title page; main text file; figures.

Title page

The title page should contain (i) a short informative title that contains the major key words. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi)

acknowledgements. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors' industrial links and affiliations. In the case of clinical trials or any article describing use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented in the following order: (i) abstract and key words, (ii) text, (iii) references, (iv) tables (each table complete with title and footnotes), (vii) figure legends. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 250 words or less the purpose, basic procedures, main findings and principal conclusions of the study. Divide the abstract with the headings: *Background and Aim, Methods, Results, Conclusions*. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to five keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine's Medical Subject Headings (MeSH) browser—(http://www.nlm.nih.gov/mesh/meshhome.html).

Text

Authors should use subheadings to divide the sections of their manuscript: *Introduction, Methods, Results, Discussion Acknowledgments and References*.

References

The Vancouver system of referencing should be used. In the text, references should be cited using superscript Arabic numerals in the order in which they appear. ADMINISTRATIVE ISSUES

Guidelines for authors

Thank you for your interest in *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully prior to submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review. Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission in accordance with the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

We look forward to your submission.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians and Pharmacists. The Journal publishes peer-reviewed original papers, reviews, meta-analyses and systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine. Papers cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor will not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer reviewed under the direction of an Editor. The Editor reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed in accordance with the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013), available at http://www.wma.net/en/30publications/10policies/b3/index.html. It should also state clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

(1) Accessible to the public at no charge;

(2) Searchable by standard, electronic (Internet-based) methods;

(3) Open to all prospective registrants free of charge or at minimal cost;

(4) Validates registered information;

(5) Identifies trials with a unique number; and

(6) includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of last follow-up, target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The journal subscribes to the principles of the Committee on

Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, with the exception of Editorials, must contain an abstract of no more than 250 words. Abstracts for original articles should be formatted into subheadings, as detailed below. Titles must not be longer than 120 characters (including spaces).

Editorials

These are invited by the Editor-in-Chief or their delegated editor, and should be a brief review of the subject concerned, with reference to and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure and cite up to 15 references, including the source article [this should be cited as Military Med. Today (year); (vol): [this issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine, and advances in clinical practice. Most published reviews are in response to editorial invitation, including thematically related “mini-series” of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are limited to 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer review process. Meta-Analyses and Systematic Reviews have a word limit of 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and/or historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Original articles are limited to 3000 words, with an abstract of up to 250 words and up to 50 references and 3–7 figures and tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Education and Imaging Coordinating Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as ‘What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?’ Part 2 will briefly describe the imaging features, particularly those that lead to diagnosis or which are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, presentation of analogous cases or related images from a similar case might be appropriate. Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background to and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors’ revised ‘Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication’, as presented at http://www.ICMJE.org/.

Spelling. The journal uses US spelling and authors should therefore follow the latest edition of the Merriam-Webster’s Collegiate Dictionary.

Units. All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations should be used sparingly and only where they ease the reader’s task by reducing repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: title page; main text file; figures.

Title page

The title page should contain (i) a short informative title that contains the major key words. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgements. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors' industrial links and affiliations. In the case of clinical trials or any article describing use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented in the following order: (i) abstract and key words, (ii) text, (iii) references, (iv) tables (each table complete with title and footnotes), (vii) figure legends. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 250 words or less the purpose, basic procedures, main findings and principal conclusions of the study. Divide the abstract with the headings: *Background and Aim, Methods, Results, Conclusions*. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to five keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine's Medical Subject Headings (MeSH) browser—(http://www.nlm.nih.gov/mesh/meshhome.html).

Text

Authors should use subheadings to divide the sections of their manuscript: *Introduction, Methods, Results, Discussion Acknowledgments and References*.

References

The Vancouver system of referencing should be used. In the text, references should be cited using superscript Arabic numerals in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or less; when seven or more list the first three followed by et al. Names of journals should be abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

References should be listed in the following form:

Number references in the order cited as Arabic numerals in parentheses on the line. Only literature that is published or in press (with the name of the publication known) may be numbered and listed; abstracts and letters to the editor may be cited, but they must be less than 3 years old and identified as such. Refer to only in the text, in parentheses, other material (manuscripts submitted, unpublished data, personal communications, and the like) as in the following example: (Chercheur X, unpublished data). If the owner of the unpublished data or personal communication is not an author of the manuscript under review, a signed statement is required verifying the accuracy of the attributed information and agreement to its publication. Use Index Medicus as the style guide for references and other journal abbreviations. List all authors up to six, using six and "et al." when the number is greater than six.

Tables

Tables should be self-contained and complement, but not duplicate, information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table, legend and footnotes must be understandable without reference to the text. Vertical lines should not be used to separate columns. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, §, ¶ should be used (in that order) and *, **, *** should be reserved for *P*-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication: Although low quality images are adequate for review purposes, publication requires high quality images to prevent the final product being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at rjmilmed@yahoo.com

A cover letter containing an authorship statement should be included.

The cover letter should include a statement covering each of the following areas:

1. Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author.
2. Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.
3. A statement outlining how ethical clearance has been obtained for the research, particularly in relation to studies

involving human subjects, and animal experimentation. The institutional ethics committees approving this research must comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.

4. For research involving pharmacological agents, devices or medical technology, a clear Conflict of Interest statement in relation to any funding from or pecuniary interests in companies that could be perceived as a potential conflict of interest in the outcome of the research.

5. For clinical trials, that these have been registered in a publically accessible database.

If the above items are not included in the cover letter, manuscripts cannot be sent for review.

Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word-files need to be included upon submission: A title page file and a main text file that includes all parts of the text in the sequence indicated in the section 'Parts of the manuscript', including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using Microsoft Word, doubled-spaced.

The top, bottom and side margins should be 30 mm. All pages should be numbered consecutively in the top right-hand corner, beginning with the first page of the main text file.

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, low-resolution figures saved as .jpg or .bmp files should be uploaded, for ease of transmission during the review process. Upon acceptance of the article, high-resolution figures (at least 300 d.p.i.) saved as .eps or .tif files will be required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted papers will be passed to production team for publication. The author identified as the formal corresponding author for the paper will receive an email, being asked to complete an electronic license agreement on behalf of all authors on the paper.

Accepted Articles

The accepted ‘in press’ manuscripts are published online very soon after acceptance, prior to copy-editing or typesetting. Accepted Articles are published online a few days after final acceptance, appear in PDF format only, are given a Digital Object Identifier (DOI), which allows them to be cited and tracked. After print publication, the DOI remains valid and can continue to be used to cite and access the article. Given that copyright licensing is a condition of publication, a completed copyright form is required before a manuscript can be processed as an Accepted Article.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing instructions on how to provide proof corrections to the article. It is therefore essential that a working e-mail address is provided for the corresponding author. Proofs should be corrected carefully; the responsibility for detecting errors lies with the author. The proof should be checked, and approval to publish the article should be emailed to the Publisher by the date indicated; otherwise, it may be signed off on by the Editor or held over to the next issue.

Offprint

A PDF reprint of the article will be supplied free of charge to the corresponding author. Additional printed offprint may be ordered for a fee.

COPYRIGHT, LICENSING AND ONLINE OPEN

Details are on the Copyright Agreement Form that must be completed and signed when the Article is accepted.

Guidelines for authors

Thank you for your interest in *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully prior to submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review. Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission in accordance with the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

We look forward to your submission.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians and Pharmacists. The Journal publishes peer-reviewed original papers, reviews, metaanalyses and systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine. Papers cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor will not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer reviewed under the direction of an Editor. The Editor reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed in accordance with the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013), available at http://www.wma.net/en/30publications/10policies/b3/index.html. It should also state clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

(1) accessible to the public at no charge;

(2) searchable by standard, electronic (Internet-based) methods;

(3) open to all prospective registrants free of charge or at minimal cost;

(4) validates registered information;

(5) identifies trials with a unique number; and

(6) includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of last follow-up, target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, with the exception of Editorials, must contain an abstract of no more than 250 words. Abstracts for original articles should be formatted into subheadings, as detailed below. Titles must not be longer than 120 characters (including spaces).

Editorials

These are invited by the Editor-in-Chief or their delegated editor, and should be a brief review of the subject concerned, with reference to and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure and cite up to 15 references, including the source article [this should be cited as Military Med. Today (year); (vol): [this issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine, and advances in clinical practice. Most published reviews are in response to editorial invitation, including thematically related “mini-series” of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are limited to 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer review process. Meta-Analyses and Systematic Reviews have a word limit of 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and/or historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Original articles are limited to 3000 words, with an abstract of up to 250 words and up to 50 references and 3–7 figures and tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Education and Imaging Coordinating Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as ‘What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?’ Part 2 will briefly describe the imaging features, particularly those that lead to diagnosis or which are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, presentation of analogous cases or related images from a similar case might be appropriate. Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background to and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors’ revised ‘Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication’, as presented athttp://www.ICMJE.org/.

Spelling. The journal uses US spelling and authors should therefore follow the latest edition of the Merriam-Webster’s Collegiate Dictionary.

Units. All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations should be used sparingly and only where they ease the reader’s task by reducing repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: title page; main text file; figures.

Title page

The title page should contain (i) a short informative title that contains the major key words. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgements. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors’

industrial links and affiliations. In the case of clinical trials or any article describing use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented in the following order: (i) abstract and key words, (ii) text, (iii) references, (iv) tables (each table complete with title and footnotes), (vii) figure legends. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 250 words or less the purpose, basic procedures, main findings and principal conclusions of the study. Divide the abstract with the headings: *Background and Aim, Methods, Results, Conclusions*. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to five keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine's Medical Subject Headings (MeSH) browser—(http://www.nlm.nih.gov/mesh/meshhome.html).

Text

Authors should use subheadings to divide the sections of their manuscript: *Introduction, Methods, Results, Discussion, Acknowledgments and References*.

References

The Vancouver system of referencing should be used. In the text, references should be cited using superscript Arabic numerals in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or less; when seven or more list the first three followed by et al. Names of journals should be abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

References should be listed in the following form:

Number references in the order cited as Arabic numerals in parentheses on the line. Only literature that is published or in press (with the name of the publication known) may be numbered and listed; abstracts and letters to the editor may be cited, but they must be less than 3 years old and identified as such. Refer to only in the text, in parentheses, other material (manuscripts submitted, unpublished data, personal communications, and the like) as in the following example: (Chercheur X, unpublished data). If the owner of the unpublished data or personal communication is not an author of the manuscript under review, a signed statement is required verifying the accuracy of the attributed information and agreement to its publication. Use Index Medicus as the style guide for references and other journal abbreviations. List all authors up to six, using six and "et al." when the number is greater than six.

Tables

Tables should be self-contained and complement, but not duplicate, information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table, legend and footnotes must be understandable without reference to the text. Vertical lines should not be used to separate columns. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, §, ¶ should be used (in that order) and *, **, *** should be reserved for *P*-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication: Although low quality images are adequate for review purposes, publication requires high quality images to prevent the final product being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at daniel_costache@yahoo.com

A cover letter containing an authorship statement should be included.

The cover letter should include a statement covering each of the following areas:

1. Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author.

2. Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.

3. A statement outlining how ethical clearance has been obtained for the research, particularly in relation to studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research

must comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.

4. For research involving pharmacological agents, devices or medical technology, a clear Conflict of Interest statement in relation to any funding from or pecuniary interests in companies that could be perceived as a potential conflict of interest in the outcome of the research.

5. For clinical trials, that these have been registered in a publically accessible database (see more under 'ETHICAL CONSIDERATIONS (Further Information)' later in these guidelines).

If the above items are not included in the cover letter, manuscripts cannot be sent for review.
